

Top 5 Open Source Firewalls

Firewalls protect your system from malicious attacks and promote privacy. This article lists the best firewalls you can choose from for your organisation.

A firewall is network security software that screens approaching and outgoing network traffic, and allows or obstructs data packets depending on a set of safety rules. It makes sure that an obstruction is built between the internal network and incoming traffic from outside sources (like the Web) to hinder malicious traffic like viruses and hackers.

There are three fundamental types of firewalls used by organisations to protect their data and devices, in order to keep destructive elements out

of the network. These are: packet filters, stateful inspection firewalls, and proxy server firewalls. Firewalls examine incoming traffic as per pre-set rules, and channel traffic coming from unsecure or dubious sources to forestall attacks. They watch traffic at a computer's entry point, called ports, which is the place where data is exchanged with external devices. For instance, source address 172.18.1.0 is permitted to reach the destination 172.18.1.1 over port 24.

Why do we need a firewall?

A firewall is a safeguard intended to shield your device from data based malware risks. A device can be anything ranging from a PC or telephone, to a tablet, TV, etc. Cyber criminals can easily probe every computer connected to the Internet and attempt to penetrate its systems. If the firewall is absent, they can easily gain access to important files, and remove or use them maliciously. The potential implications of this can be disastrous, often leading to considerable financial
