

New open source software to enhance home Wi-Fi coverage from Prpl Foundation

Prpl Foundation, a community-driven consortium for open source network architecture, has announced the release of its prplMesh 2.0 software stack, eligible for Wi-Fi Alliance (WFA) EasyMesh Release 2 certification, for both agent and controller roles.

“The mission of the prplMesh project is to create a carrier-grade, production-worthy, open source solution for managing Wi-Fi Access Points in CPE gateways and Wi-Fi Mesh Extenders, to provide best-in-class Wi-Fi coverage and seamless user experience,” the company said in a release.

Len Dauphinee, president of the prpl Foundation, said, “Service providers increasingly rely on open source software solutions to best manage the complexity of supporting, updating, and remotely managing their disparate inventory of various CPE devices deployed in the field. This second release of prplMesh further enhances the Wi-Fi experience for both service providers and their subscribers with new features that improve the capacity, functionality and manageability of smart mesh networks deployed in homes.”

The prplMesh stack is platform-independent, leveraging open standards and open APIs, and is currently ported onto both prplWare and RDK-B router operating systems. Subscribers will enjoy prplMesh deployments that provide true whole-home Wi-Fi coverage through easy installation of self-organising smart routers and Wi-Fi extenders distributed throughout their homes.

compute offering to complement the company’s existing Infrastructure-as-a-Service (IaaS) and Platform-as-a-Service (PaaS) offerings, which target developers in small

and medium-sized businesses (SMBs).

Serverless enables rapid development and deployment, allowing businesses to significantly reduce development costs and increase productivity without sacrificing performance to support their use case.

Nimbella was designed specifically to address the challenges developers face in adopting serverless computing. It builds on Kubernetes and Apache OpenWhisk, both of which are mature production-ready open source projects.

“Serverless computing is the next evolution of the cloud that further removes the need for developers to manage complex infrastructure. We are excited to have Nimbella join DigitalOcean to address specific needs often requested by our customers and fill a gap in the current serverless offerings in the market,” said Yancey Spruill, CEO at DigitalOcean. “People want to access the benefits of serverless capabilities without a significant learning curve, and they want functionality and pricing that is easy to understand and predictable. Nimbella provides all of this with the same simplicity and open source software standards that are core value propositions for DigitalOcean.”

Terms of the transaction were not disclosed and there is no change to DigitalOcean’s 2021 financial outlook as a result of the acquisition. DigitalOcean plans to fully integrate the Nimbella serverless offering and launch the product under its brand name in the first half of 2022.

Kubescope to run Kubernetes hardening tests

ARMO has released Kubescope, the open source tool for testing, if Kubernetes is deployed securely as defined in Kubernetes Hardening Guidance by National

Security Agency (NSA) and the Cybersecurity and Infrastructure Security Agency (CISA).

Kubescope can be used to test clusters or scan single YAML files and integrate them to processes. It can run the following tests: non-root containers, immutable container file system, building secure container images, privileged containers, hostPID and hostIPC privileges, hostNetwork access, allowed hostPaths field, protecting pod service account tokens, pods in kube-system and kube-public, resource policies, control plane hardening, encrypted secrets and anonymous requests.

It is based on the open policy agent (OPA) engine and ARMO’s posture controls. According to the project’s maintainers, Kubescope retrieves the Kubernetes objects from the API server and scans them by running a set of regos snippets developed by ARMO.

The results of the tests get printed in a ‘console friendly’ manner by default, but they can also be retrieved in JSON format for further processing.

“Kubescope is an open source project. We welcome your feedback and ideas for improvement. We’re also aiming to collaborate with the Kubernetes community to help make the tests themselves more robust and complete as Kubernetes develops,” the maintainers wrote on the project’s GitHub page.
