

But what if you want to treat a trigger word to be a normal one? For that, you can just use the backspace key to prevent the word substitution and preserve the trigger word just as it was typed.

If you want to use Espanso as an automatic correction tool you must be careful, because whatever you're defining in the replace part should affect only the exact word in the 'trigger'. For example, if you often type the name *dodd* as *dod* incorrectly, and you write the following code:

```
- trigger: "dod"
  replace: "dodd"
```

...every time you type *dod* it will be replaced by the word *dodd*, just as you intended. But the problem here is the word *dodge* partially matches with your trigger; so when you try to type *dodge* after typing its first three letters, they will be replaced by the word *dodd*. And that is something not intended. This can be solved by adding a line to the above code as:

```
- trigger: "dod"
  replace: "dodd"
  word: true
```

The last line instructs that replacement should happen only if the trigger is a separate word. So if you're using *dod* and *dodge* in the same sentence, only the word *dod* will be replaced as *dodd*, but the word *dodge* will remain as it is.

Another neat feature in Espanso is that be shown in the same case as the trigger word added in the text area.

For example, suppose you want the trigger word *westros* in the same case as it is being typed in (lower case, sentence case or upper case).

In the *default.yml* file, add the following lines:

```
- trigger: "westr"
  replace: "westros"
```

```
propagate_case: true
word: true
```

The above code will replace the case of the word exactly as it is typed – for example, *Westr*, *westr*, *WESTR* will be replaced as *Westros*, *westros*, *WESTROS*.

Images

Espanso doesn't limit itself to text alone. It can also insert an image from your triggers. To add an image in your text, insert the following code in your *default.yml* file:

```
- trigger: "pic_sam"
  image_path: "/home/magimaiprakash/
  Pictures/sam.jpg"
```

Here, the only requirement is that you need to provide the location of the image. This will come in handy when you want to add personal photos or company logos, etc.

Shell commands

In Espanso, you can actually replace the shell command by specifying a trigger. For example, if you want to know the version of the Ruby programming language installed in your system, insert the following code in the configuration file:

```
- trigger: "ruby version"
  replace: "{{output}}"
  vars:
    - name: output
      type: shell
      params:
        cmd: "ruby -v | awk '{print $2}'"
```

The above code will produce the version of the Ruby interpreter:

```
ruby 2.7.2p137
```

Scripts

Sometimes you may need to execute external scripts that may be required in your text. To do this, you can use

the Script extension. A typical 'Hello world' program in Ruby can be executed by the following code:

```
- trigger: "hello_ruby"
  replace: "{{output}}"
  vars:
    - name: output
      type: script
      params:
        args:
          - ruby
          - "/home/kmp/.config/
  espanso/user/scripts/hello_ruby.rb"
```

This will produce the following output:

```
Ruby Says Hello
```

Forms

Espanso is capable of creating simple forms. These are extremely useful when you're using static and dynamic elements. So, for example, if you want to send out a birthday wish, you can use forms to keep a constant birthday message with only the names changing.

A simple form for birthday wishes can be created with the following snippet:

```
- trigger: ":bday_greet"
  form: |
    Hey {{name}},
    {{text}}
    Happy Birthday!
```

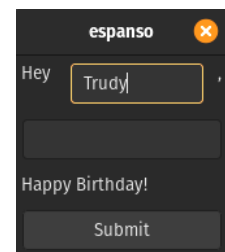

Figure 1: Birthday wish form

After reloading the configuration, whenever you type *bday_greet*, a small form will open; you need to enter the name of a person, and it will produce the

following output:

```
Hey Trudy,
Happy Birthday!
```
