

Setting Up a Virtual Private Cloud Using Eucalyptus

Learn how to turn your laptop into a virtual private cloud with this simple tutorial.

A virtual private cloud (VPC) is essentially a pool of shared resources hosted within a public cloud. By building a VPC, we can create different virtual machines. Eucalyptus is a platform that aids in the creation of cloud services. It is used by several cloud service providers, notably Amazon, to deliver cloud services. In this article we will find out how to set up a VPC using Eucalyptus.

Let us start

First, install the operating system. We can either install it in a separate partition on our hard disk or on virtualisation software like VMware or Virtualbox. You can get the ISO image file from <https://drive.google.com/file/d/1UION-home5vZWmjJWXXAq17k7Gg6DXjz/view>.

Once you download the ISO file, install the operating system. It is pretty self-explanatory. You need to just follow the steps, and choose CentOS 6 with Eucalyptus Cloud-in-a-box.

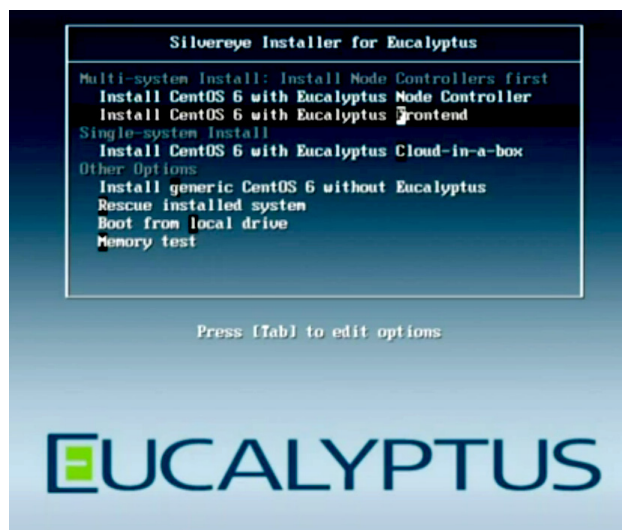

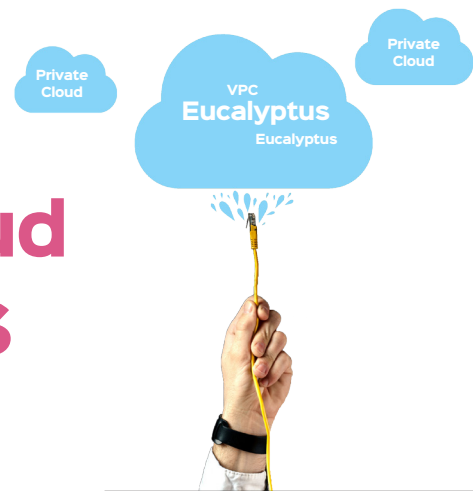

Figure 1: Installation

Once the installation is done, you can create the VM. While installing the OS, note the user name and password. Restart the machine once the installation is done and log into it.

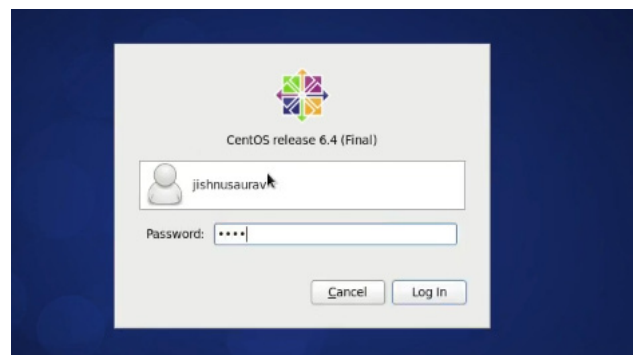

Figure 2: Log in

Now choose the Eucalyptus user control from the desktop, and use the login details that were obtained while installing the Eucalyptus image (as shown in Figure 2 and Figure 3). Then your screen will look like what's shown in Figure 4, just as it appears in Amazon Cloud Services. You can now use your private cloud as a service.
