

GitHub announces recipients of the open source grants

At GitHub Satellite India 2021 earlier this year, the company announced GitHub Open Source Grants, committing Rs 10 million to support and fund open source maintainers and contributors, as they continue to build open source software and make an impact for India and the world. Developers from 81 cities and 19 states across India applied, and showcased their open source projects. Since May 2021, GitHub has received hundreds of applications from across the country, and has been working hard to continue to expand these programmes that support and fund developers in India.

The company has announced the first 15 recipients of GitHub Open Source Grants: liyasthomas, anuraghazra, pranshuchittora, VishalNehra, bodhish, shivammathur, ahiliation, onprem, ptrthomas, akshay2211, snitin315, anikethsaha, shikhamis11, gautamkrishnar, and gdsoumya.

Maneesh Sharma, general manager, GitHub India, said, “This is why we introduced GitHub Sponsors, and I am excited to share that we are starting to open up GitHub Sponsors to an initial group of developers—including our grant recipients in India.”

Sharma added, “Indian developers are truly building the future of software, making India an innovation powerhouse, with open source software development at the core. I am so excited to celebrate the impact that Indian developers are making in the country and beyond. We will continue to support and fund open source maintainers and contributors in their important work through our GitHub Open Source Grants and Sponsors programmes.”

Nearly 13 million malware events targeted Linux based cloud environments in the first half of 2021

Trend Micro Incorporated, a cyber security firm, has released new research on the state of Linux security in the first half of 2021. The report gives an insight into how

Linux operating systems are being targeted as organisations increase their digital footprint in the cloud, and the pervasive threats that make up the Linux threat landscape.

Linux allows organisations to make the most of their cloud based

environments and power their digital transformation strategies. Many of today's most cutting-edge IoT devices and cloud based applications and technology run on some flavour of Linux, making it a critical area of modern technology to secure.

“In the industry, we see some very creative attacks and we have to stay ahead. Protecting the company, our employees, and our intellectual property is a priority,” says John Breen, global head of cyber security at Flowserve. “We’ll continue to work closely and collaborate with Trend Micro to ensure our people and our company remain protected.”

The report investigates the top malware families affecting Linux servers during the first half of 2021, with the top types of malwares being:

Coin miners (25 per cent): The high prevalence of cryptocurrency miners is of little surprise given the clear motive of the seemingly endless amount of computing power the cloud holds, making it the perfect environment.

Web shells (20 per cent): The recent Microsoft Exchange attack, which leveraged Web shells, showed the importance of patching against this type of malware.

Ransomware (12 per cent): The most prevalent malware detected was the modern ransomware family, DoppelPaymer; however, some other notable ransomware families seen targeting Linux systems as well are RansomExx, DarkRadiation, and the DarkSide.

“It’s safe to say that Linux is here to stay, and as organisations continue to move to Linux based cloud workloads, malicious actors will follow,” said Aaron Ansari, vice president of cloud security for Trend Micro. “We have seen this as a main priority to ensure our customers receive the best security across their workloads, no matter the operating system they choose to run it on.”

The report revealed that most detections arose from systems running end-of-life versions of Linux distributions, including 44 per cent from CentOS versions 7.4 to 7.9. In addition, 200 different vulnerabilities were targeted in Linux environments in just six months. This means attacks on Linux are likely taking advantage of outdated software with unpatched vulnerabilities.

Mirantis announces availability of Mirantis OpenStack 21.4

Mirantis has announced the availability of Mirantis OpenStack 21.4, which includes a number of important enhancements that enable enterprises to support a broader range of deployment options, extend private clouds over public networks, and provide long-term support for OpenStack Victoria.

Mirantis OpenStack 21.4 enables support for centrally managed, distributed edge deployments. As companies move to modernising their IT infrastructure, there are requirements to distribute portions of the data centre compute or storage
