

infrastructure at the edge, as close to their users, or as close to the source of the data, as possible. Mirantis OpenStack makes edge deployments viable because it needs half the nodes required for a traditional deployment and centralises management of distributed, remote resources.

Adam Parco, Mirantis CTO, said, “The latest release of OpenStack creates a number of unique challenges due to the constraints for the deployment of a sufficiently scaled data centre, in terms of space, power, cooling and other related factors, as well as the management of distributed data-centre clusters. Traditional distributed management solutions have been relatively resource-heavy when

compared to that available in a small edge data centre, making such a deployment less than viable.”

TrueConf introduces Linux based video collaboration platform

TrueConf has announced the official release of TrueConf Server for Linux. This platform will enable organisations with Linux based infrastructure to deploy highly secure video conferencing networks using the ecosystem of TrueConf software and hardware solutions. The Linux version of TrueConf Server ensures the same security, quality, and feature set as its counterpart for Windows. Users can run unlimited UltraHD events with up to 1,000 participants at a time, from any location and device.

TrueConf Server for Linux is currently available on Debian 9/10 and CentOS 7/8, with more operating systems in the pipeline. It complements a wide range of already supported distributives for TrueConf for Linux client apps, such as Ubuntu, Fedora, Mint, Arch, and many others.

Dmitry Odintsov, CEO at TrueConf, said, “We’re glad to release TrueConf Server for Linux that is going to raise the bar for intra-corporate communication security. Thanks to Linux support, our customers can significantly reduce the cost of designing and maintaining IT infrastructures as they no longer need to purchase server licences and Microsoft CALs for users and devices on the company network. And their staff members can enrich remote teamwork with cutting-edge collaborative capabilities of a TrueConf video meeting solution.”

He added, “Extended interoperability of TrueConf Server will facilitate integration of video communication technologies into corporate IT infrastructures built on both Microsoft and Linux operating systems. By combining security-specific

Linux components with TrueConf privacy protection capabilities, both SMBs and enterprise-grade entities can now deploy a reliable video conferencing network that meets the most stringent security standards.”

Elastic announces the general availability of the

Asian Development Bank and Alliance Bank adopt Red Hat Ansible Automation Platform

Red Hat, Inc. has announced that Alliance Bank (Malaysia) and the Asian Development Bank (Philippines) have adopted Red Hat Ansible Automation Platform as their enterprise grade, agentless automation platform in their journey to the cloud. According to a 2020 Forrester report commissioned by Red Hat, automation is also an organisational necessity — three out of five respondents reported automation as one of their firm’s top initiatives, even amid competing priorities like adoption of cloud, containers and security management.

The two banks are examples of financial services organisations in Southeast Asia that are deploying Red Hat Ansible Automation Platform to automate repetitive and manual tasks, orchestrate complex workflows, improve processes, and offer agility to deploy applications faster with fewer human interventions.

Asian Development Bank (ADB) was looking into automation solutions that would improve operational efficiency and effectiveness by automating repetitive tasks. Alliance Bank wanted to automate manual tasks such as server configuration, patching and hardening in order to free up team bandwidth away from resource-heavy tasks. Starting with server hardening and patching, Alliance Bank then added disaster recovery (DR) automation to protect their core systems and build readiness as their hybrid cloud environment expanded. Red Hat automated the DR process and created a playbook to make this process repeatable and scalable. This is resulting in better uptime of Alliance Bank’s applications when they run DR processes.
