

# Setting Up a Backup System with Bacula

Data loss can occur for a variety of reasons, including technology problems, human error, physical theft, or ransomware. In this article we will see how Bacula, an application that helps us to back up crucial data, works.

Data backups are often stored in secure locations like the cloud. All organisations need to back up important data regularly including customer databases, machine and OS images, and even registry files. Most IT companies have a whole department to take care of this.

Data backups can be done in many ways such as by using physical devices and cron jobs. There are also many applications like Amanda, Bacula and BackupNinja that help in accomplishing this task. In this article, we will set up a basic Bacula backup system in order to see how it works.

Bacula is an enterprise level, open source computer backup system that can be used in networks, and has been designed in such a way that backup tasks are automated. Earlier, this required an admin or computer operator to do the same. We can also use Bacula to store the backup on a different machine or even a different network.

## Setting up a basic Bacula backup system

To set up a basic Bacula backup system on a Linux machine, first install the MySQL server, Bacula server and the Bacula client.

But before that, update the packages using the following command, as shown in Figure 1:

```
jishnu@jishnu-VirtualBox:~$ sudo apt-get update
[sudo] password for jishnu:
Hit:1 http://in.archive.ubuntu.com/ubuntu bionic InRelease
Hit:2 http://in.archive.ubuntu.com/ubuntu bionic-updates InRelease
Hit:3 http://in.archive.ubuntu.com/ubuntu bionic-backports InRelease
Hit:4 http://security.ubuntu.com/ubuntu bionic-security InRelease
Reading package lists... Done
```

Figure 1: Updating the packages

`sudo apt-get update`

Once this is done, just run the following commands, as shown in Figures 2 and 3.
