

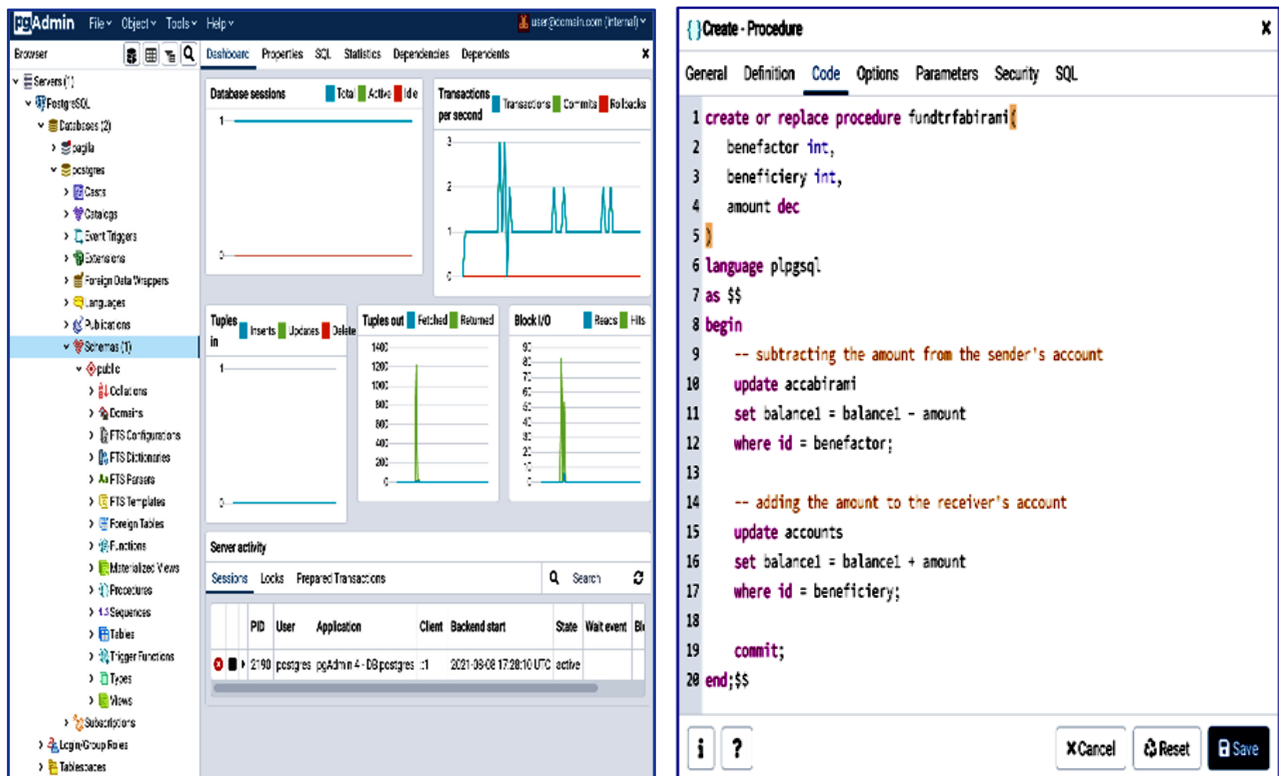

Figure 3: PGAdmin interface

Advantage 4: Coordination between memory, utility process and physical file ensures redundancy, availability and high performance

Postgres is often criticised for the crudeness of its UI control, which makes it heavily scripted for administration and development. However, this challenge is also overcome by Postgres with the help of PgAdmin, which is a feature-rich platform enabling ease of administration and development, and PgAgent, which aids UI based scheduling and monitoring.

The data types supported by Postgres exceed what any RDBMS can offer. To name a few: numeric, monetary, binary, date time, Boolean, enumerated, geometric, network address, bit string, UID for unique identifier, XML, JSON, array, composite, range, object identifier and pseudo. These are categories of data types within which multiple data types are offered.

Standard and non-standard procedural languages provided by this platform include PL/PgSql, PL/Python, PL/Java, PL/JavaScript, PL/Perl, PL/UNIX like Sh, PL/Ruby, PL/R, PL/PHP, PL/Parrot, PL/OpenCL (for GPU enabled functions), and a dozen others.

The platform supports simple querying, CRUD (create, read, update, delete) as well as complex analytics. A strong community backing, which constantly endeavours to

enhance and support the platform, gives the encouragement that developers and administrators need to invest more energy in building their solutions on it.

Microsoft Azure, too, has come up with managed Postgres, which takes away the administrative overhead, while offering enterprises scale.

Advantage 5: Great interface, wide ranging features and a strong community

More and more institutions are embracing Postgres for its friendly interface, versatile features and great community, making it an easy inclusion in enterprise scale architecture.

The above advantages are only illustrative of the range of offerings this platform has, but they do indicate why PostgreSQL is looked upon as the most advanced open source database.
