

Figure 13: Add module Webform

information, a slide in a slide show, etc. Each of these make up a content type. We can alter the data structure of each content type so that it has all the relevant information captured in the best way.

To create your own content type, from the admin menu on top, click on *Structure* and from the list shown, click on *Content types*. This will now show you a list of the content types that are present in the system.

You can add a new content type, edit the fields that are a part of it, and even decide which fields are to be shown and which hidden (Figure 9).

Taxonomy

Another important aspect of arranging content on a CMS is categorising features. Using Drupal's inbuilt taxonomy system, one can easily create vocabularies and associate them with the various contents on the system. These could be a pre-entered list of terms or a free tagging system. Content can then be easily categorised, sorted and filtered using the terms associated with it. You can see them as a list of taxonomies and terms. To view them, click on *Structure* from the admin menu and then on *Taxonomy*. This will show a list of the taxonomies in the system and then you can click to add or view more terms.

To add it to the contents, just make a *Taxonomy Term* field as a part of the *Content type*, to capture which category is associated with the content added.

Users

No digital system is complete without its users. Drupal's inbuilt user module provides a very good solution for users to be registered on the system and role based permissions to be assigned to them. You can extend the information about a user by adding more fields into the user's profile information. From the top user menu, click on the *My account* link to view your user profile (Figure 10).

To check the list of users registered on the system, click on the *People* link from the admin menu (Figure 11).

To add more roles or assign special permissions to each role, click on the *Permissions* tab in the *People* page that you opened right now.

Menu and path system

In Drupal, every path lands at a unique page that runs a set of functions to create the content and structure for that page. This could be individual content, a list of contents, a list of users, the *Home* page with aggregated content from the rest of the site, a form and more. In order to make the URLs user friendly, URL aliases are used and mapped to these paths generated by the Drupal system.

Next, you can create a list of the paths to build a menu and display it as the main menu or a user menu, secondary side navigation menu and more. Go to *Structure* from the admin menu, and click on *Menus* to view the list of menus and a list of links added to each menu (Figure 12).

Modules

The module system of Drupal is at the heart of its extensibility. The plain Drupal installation has some core features and a hook based system that helps other added modules to extend its features. These additional features are packaged into modules that can be added and enabled as per requirements. Some examples could be: a *Commerce* module to enable commerce capabilities, a 'Five Star' rating, CKEditor, Devel for debugging and more. There are close to 30,000 modules that have been published on www.drupal.org, which can be added to your Drupal site to enhance its features.

Go on and try one. Let's try the Webform module at <https://www.drupal.org/project/webform>.

Go to the URL and download the *.tar.gz* or *.zip* file. Unzip it and extract the contents into the *sites/all/modules/contrib* folder within the *docroot* of your Drupal site. Now, from the top admin menu, click on the *Modules* page link. This should show you a list of modules with this new module that can be selected to be enabled and installed.

As seen in Figure 13, the system checks if there are any dependencies for installing this module. You can see that it requires two other modules, *ctools* and *views*, to be installed too. So quickly download them from <https://www.drupal.org/project/ctools> and <https://www.drupal.org/project/views>, respectively and extract them into the *sites/*
