

```
'route' => '/add',
'defaults' => array(
    '_NAMESPACE_' => 'Application\
        Controller\Index',
    'action'       => 'index',
),
),
'may_terminate' => true,
'child_routes' => array(
    'default' => array(
        'type' => 'Method',
        'options' => array(
            'verb' => 'post',
            'defaults' => array(
                'action' => 'post'
            ),
        ),
    ),
),
),
),
),
)
```

6. Part: Part routers are nothing but parent-child routes. In any router type, parent-child routing becomes a part router.

7. Scheme: This is like literal routing but only matches the scheme part of the URI.

```
'router' => array(
    'routes' => array(
        'scheme-route' => array(
            'type' => 'Zend\Mvc\Router\Http\Scheme',
            'scheme' => 'https',
            'options' => array(
                'route' => 'admin.todo-local.com',
                'defaults' => array(
                    'https' => true
                ),
            ),
        ),
    ),
)
```

Matched routes

In *Module.php*, we can get a matched router definition based on a request. We can attach an event listener that is executed after routing. The code below is for getting matched router information:

```
public function onBootstrap(MvcEvent $e)
{
    $eventManager = $e->getApplication()->getEventManager();
    $routeMatch = $e->getRouteMatch();
```

```
$controller = $routeMatch->getParam('controller');
$action = $routeMatch->getParam('action');
$namespace = $routeMatch->getParam('__NAMESPACE__');
}
```

Using routes in a controller

You can get route parameters as follows:

```
public function indexAction(){
    $id = $this->params()->fromRoute('id'); //specific
parameter name
    $all = $this->params()->fromRoute(); //all parameters
}
```

To redirect to route, type:

```
public function indexAction(){
    return $this->redirect()->toRoute('home-route');
}
```

To use routes in *View*, type:

```
<a href='<?php echo $this->url('home');?>'></a>
```

Now let's implement this in our application.

Creating an admin module

All master admin related tasks will be implemented here. To create modules and controllers, the developer community provides ZFTool—a command line tool to generate the module, controller, action and more. You can find ZFTool at the URL <https://github.com/zendframework/ZFTool>. You can install it either manually or by using the composer. The instruction manual can be found at <http://framework.zend.com/manual/current/en/modules/zendtool/introduction.html>.

Creating an admin host router

As described earlier, we will create an admin host router to access admin related tasks only.

```

    'router' => array(
        'routes' => array(
            'admin' => array(
                'type' => 'Zend\Mvc\Router\Http\Hostname',
                'options' => array(
                    'route' => 'admin.todo-local.com',
                    'defaults' => array(
                        'controller' => 'Application\
Controller\Auth',
                        'action' => 'index',
                    ),
                ),
            ),
        ),
    ),
),
);

```
