[root@deepu ns3]#
[root@deepu ns3]# grep -r "netanil.tr" | grep "/NodeList/2/" | wc -l
46
[root@deepu ns3]# ./packet_count.awk netanil.tr
No of packets received at the destination = 46

[root@deepu ns3]# ./packet_count.pl netanil.tr
No of packets received at the destination = 46

```

Figure 2: Execution of trace analysis scripts

```

open (DATA,"<$infile") || die "File $infile Not Found";
$counter=0;
while(<DATA) {
    @x = split(' ');
    if($x[0] eq 'r')
    {
        if($x[2] =~ /NodeList/2/)
        {
            $counter=$counter+1;
        }
    }
}
printf "\n\nNo of packets received at the destination = %d\n\n", $counter;
close DATA;

```

```
exit(0);
```

The working of the Perl script is similar to that of the AWK script. In the script given above, '@x' is an array variable containing a line of data from the trace file. The variable '\$x[0]' contains the first field of a line of data, which is regarding the event type. Similarly, '\$x[2]' contains the third column of the trace file, and this corresponds to the third line of the trace file sample. Thus the Perl script also counts and reports the number of packets received at node 2. The execution of the three different scripts discussed in this section is shown in Figure 2.

But the scripts will get executed only if your system contains executable files of Perl and AWK. Open a terminal and execute the command 'echo \$PATH'. A number of directory names with a complete paths will be displayed. Make sure that the executable files of AWK and Perl are available in any one of these directories. The executable files are named 'awk' and 'perl'. If your system doesn't have these files, install AWK and Perl. **END**
