

How to build an app using Django and Python

Let's build a simple application that will calculate the BMI (body mass index), for which you just need to provide your height and weight as input. In this example, the name of the application is BMI_Calculator.

First, create a new application using Eclipse. Go to Eclipse -> New project->PyDev Django.

Right click on the root folder -> Django -> Create new application. You will be able to see a few sub-folders inside the root folder.

Below is the code for View.py:

```
# Create your views here.
from django.http import HttpResponseRedirect
from django import forms
from django.shortcuts import render
from django.core.context_processors import request
def form_print(request):
    return render(request, 'firstform.html', {})

def form_get(request):
    height=request.POST.get('height','')
    weight=request.POST.get('weight','')
    weight=float(weight)
    height=float(height)
    BMI = weight/(height*height)

    weight=str(weight)
    height=str(height)
    BMI=str(BMI)

    return HttpResponseRedirect("Your Height =" + height + "meter " +
    + " Your Weight =" + weight + "KG " + " Your BMI =" +
    BMI )

urlpatterns = patterns('',

    url(r'^form_print/$', form_print),
    url(r'^form_get/$', form_get),
)

Setting.py
Make changes in TEMPLATE_DIRS and INSTALLED_APPS
PACKAGE_ROOT = os.path.abspath(os.path.dirname(__file__))

TEMPLATE_DIRS = (

    os.path.join(PACKAGE_ROOT, "templates")
```

```
)
```

```
INSTALLED_APPS = (
```

```
    'BMI_Calculator',
```

```
)
```

Keep *Firstform.html* file in the template folder (you can create one inside the root folder).

```
<html>
<body>
<form action="/form_get/" method="POST">{% csrf_token %}
Height:<br>
<input type="text" name="height" value="Height in Meter">
<br>
Weight:<br>
<input type="text" name="weight" value="Enter your weight in
KG">
<input type="submit" value="GET BMI">
</form>

<p>BMI = body mass index</p>
<p>Under Weight => BMI < 18.5</p>
<p>Normal Weight => BMI >= 18.5 <= 24.9</p>
<p>Over Weight => BMI > 25 < 30</p>
<p>Obesity => BMI > 30</p>
</body>
</html>
```

Figure 1: BMI calculator

You can refer to Figure 1 to see the output of the above code.
