

Creating an Audio and Video Player using jPlayer

This tutorial walks the reader through the process of creating a basic audio/video player on a website and then customising it to add more features. The tutorial carries the required code and so makes this an interesting and doable project!

jPlayer is an open source plugin developed on jQuery, and provides a highly extensible and standardised way of embedding audio/video media on a website. This article will guide the reader on creating a basic audio or video player and then customising it. The procedure has been divided into three simple steps:

1. Creation of the basic layout
2. Adding audio files in the form of a playlist using jPlayer
3. Customising the player (adding a theme auto-generator)

Get jPlayer

Before starting any development, we need to download the jPlayer plugin from <https://github.com/happyworm/jPlayer> and include the following two JavaScript files in our code to provide the required features:

- `Jquery.jplayer.min.js`
- `jPlayer.playlist.min.js`

Creating the basic layout

Let's use the `<div>` tags to create a basic template for the audio player. First, we need a master `<div>` that will enclose the player with all control buttons, progress bar, volume control buttons, etc. Then, we create the basic *Play/Pause* and *Stop* buttons to provide the basic features.

```
<div id="jp_container_1" class="jp-video jp-  
video-270p" role="application" aria-label="media  
player">  
  <div class="jp-type-playlist"> </div>  
</div>
```
