

The Basics of MVC Architecture in PHP

MVC, which stands for Model-View-Controller, is a really good way to develop clean, scalable, powerful and fast applications in the least amount of time and with the least effort. Before exploring MVC, this article begins with a brief introduction to PHP.

PHP is an open source programming language that was developed in 1994 by Rasmus Lerdorf. PHP originally stood for *Personal Home Pages* but now stands for *Hypertext Preprocessor*, which is a recursive acronym. It is a loosely typed server-side scripting language used to build Web applications. A scripting language is a language that does not need to be compiled before use. And 'loosely typed' languages are those in which there is no need to define the type of a variable.

Today, more than 20 million domains use PHP, including

Facebook and Yahoo.

PHP is easily embedded with HTML, and is used to manage dynamic content and the databases of websites or, we can say, Web applications. We can use PHP with many popular databases like MySQL, PostgreSQL, Oracle, Sybase, Informix and Microsoft SQL Server.

How PHP works on servers

When a client (browser) sends a request for a PHP page to the server, the server reads the requested file from the disk
