

Figure 8: Meteor events

Meteor also supports all types of HTML DOM events.

Note: *preventDefault()*: prevents the action the browser would normally take in response to this event, such as following a link or submitting a form. Further handlers are still called, but cannot reverse the effect.

Methods

Meteor methods are like functions in JavaScript with a different syntax. They can be called by the client as well as by the server.

Let us now look at how to create methods in Meteor.

```
Meteor.methods({
```

```
'foo': function(){
  console.log("Hello world, I am Method");
}
});
```

Every method has a method name and is associated with a function, which is executed when the method is called.

The *Meteor.call()* method is used to trigger the execution of the method. We pass a parameter in the *Meteor.call()* method which is the name of the method to be called. Shown below is the syntax to call the method *foo*.

```
Meteor.call('foo');
```

Meteor methods can accept parameters and also return a value. **END**
