management tool that lets you define security policy at a higher level of abstraction, and hides the internal structure of the target firewall platform. The main advantage of *fwbuilder* is that it implements industry-wide accepted practices in policy design, and helps users deploy the policies on each firewall.

Firewall Builder is, by default, available for all versions of Debian and Ubuntu. It is also available as an extra package for Fedora Core. I'll be using Fedora Core 12 as my firewall

manager system. (The firewall manager is a machine from where you manage the cluster and distribute the policy.)

For installation on Fedora 12, you either can install the stable package of *fwbuilder* with dependencies using *yum*, or can install the individual RPMs. Create the file */etc/yum.repos.d/fwbuilder.repo*, and add the following entries:

```
[fwbuilder]
name=Firewall Builder
baseurl=http://www.fwbuilder.org/rpm/stable/fedora-$releasever-$basearch
enabled=1

[fwbuilder-testing]
name=Firewall Builder Test Builds
baseurl=http://www.fwbuilder.org/rpm/testing/fedora-$releasever-$basearch
enabled=0
```

**Note:** If you would like to use any RHEL system as the firewall management machine, replace "fedora" with "rhel" in the above baseurl lines.

Now run the following command:

```
[root@FirewallManager ~]# yum install fwbuilder
```
