

Figure 4: Splash screen

Figure 5: Login page

Figure 6: Login validation

```
Cursor cursor = null;
try{
    //SELECT _id FROM login WHERE username=uname AND
    password=pass
    cursor = db.query(DbHelper.SAKET_TABLE_NAME, columns,
        selection, selectionArgs, null, null, null);
    startManagingCursor(cursor);
} catch(Exception e){
```

```
    e.printStackTrace();
}
int numberOfRows = cursor.getCount();
if(numberOfRows <= 0){
    Toast.makeText(getApplicationContext(), "Login Failed..\\nTry
Again", Toast.LENGTH_SHORT).show();
    return false;
}
return true;
}
```

In this method, we will be using the built-in database APIs offered by Android to perform database operations. First, we need to create an instance of a class called *DBHelper*, to connect to our database, so that we can use it. To operate on a database, we need to follow the sequence given below:

- Open a database
- Read/write operations on a database
- Commit
- Close the database.

Following the same order, we open the database using the *getReadableDatabase()* or *getWritableDatabase()* methods, based on the required mode of operation. We can use a generic *SQLiteDatabase* instance, which is returned by the *getReadableDatabase()* method. Now that we have the database object, we need to perform a query on it to validate the user credentials in the database. Thus, we need to code the query as follows:

```
public Cursor query (String table,
String[] columns,
String selection,
String[] selectionArgs,
String groupBy,
String having,
String orderBy
)
```

These variables are for the following purposes:

- *columns*: the columns that are requested in the SELECT statement.
- *selection*: the WHERE clause of the statement
- *selectionArgs*: the values of the place-holders in the selection string.
- *groupBy*: the SQL GROUP BY clause.
- *orderBy*: ORDER BY clause.

Our query hence becomes what's shown below:

```
db.query(DbHelper.SAKET_TABLE_NAME,
columns,
selection,
selectionArgs, null, null, null);

columns = _id
```
