

Figure 11: The final form

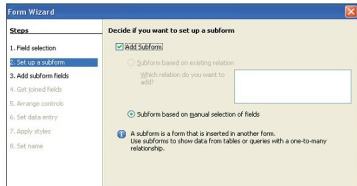

Figure 12: Form wizard window with option to add subform is selected

In the *photo* field, just enter the name of the corresponding image file (for example, *riya.jpg*, *binay.jpg*, etc).

So far, the form does not display the photograph; so let's try to add that feature in a copy of this form. In the *Forms* view of the database, copy the *empdetails* form (Ctrl-C) and paste it (Ctrl-V); give it the name *empdetailsview*. Open this form in *design view* (right-click and choose *Edit*), and add an image field from the tool-box. Double-click the image field to open the *Properties* window. Select the *Data* tab, and choose the *photo* field from the drop-down menu. Save the form. The final result will be as shown in Figure 11.

Database relationships

Let's suppose I want to record the working hours of our employees on different dates. I create a table named *hrsbooking* containing the following fields:

Name of field	Type of field
id	Integer (INTEGER)
empid	Integer (INTEGER)
date	Date (DATE)
hrs	Integer (INTEGER)

We need not define redundant fields like the name of the worker, address, and other details, because those are already stored in the *empdetails* table. Using the *empid* field that's common to both tables, we can define a relationship between the two tables. For each employee (single row in the *empdetail* table), there can be, and probably will be, multiple records in the *hrsbooking* table. This is known as a *one-to-*

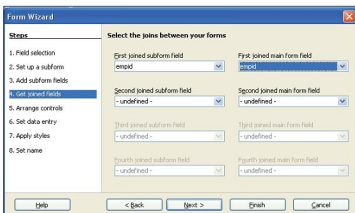

Figure 13: Screenshot showing relationship between two tables

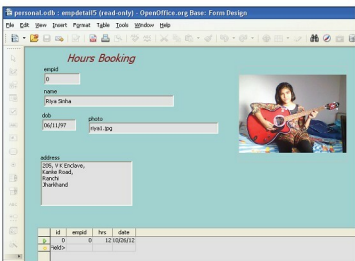

Figure 14: Form with a subform

many relationship. There are also *one-to-one* and *many-to-many* types of relationships.

For data entry into the *hrsbooking* table, let's create a new form that combines both the *empdetail* and *hrsbooking* tables, related on the common field *empid*. Launch the *Form wizard*. Select the *empdetail* table and add all its fields, as before. Click *Next*. This time, tick *Add Subform*, as shown in Figure 12. Select *Subform based on manual selection* and click *Next*. Select the sub-form table *hrsbooking*, and all its fields before clicking *Next*. To define the relationship, select *empid* from *First joined subform field*, and also in the *First joined main form field* drop-down and then click *Next*.

In the subsequent steps of the wizard, keep the default selection. Save the form as *formdetail5*. Open the form in *Edit* mode, and include an image field as earlier. Finally, you should have a form like what's shown in Figure 14 (but with your own customisation). Enter some data into the *hrsbooking* table for some of your employees, to see how it works.

Queries

Queries are used to view records, possibly filtering data, restricting the fields displayed, and/or retrieving a combined set of data from multiple tables. We will design
