

through Java Web Start (JNLP). In this approach, the user will log in to the slave node, open a browser and open the slave page by pointing to the URL of the master system. It may look like the following URL: `http://masterserver:PORT/hudson/jnlpJars/slave.jar`

You are then presented with the JNLP launch icon. If you click on the icon, the Java Web Start kicks in and it launches a slave agent on your computer.

This mode is convenient when the master cannot initiate a connection to slaves, such as when it runs outside a firewall while the rest of the slaves are within the firewall. The disadvantage is, if the machine with a slave agent goes down, the master has no way of re-launching it on its own.

Launching a slave agent 'headlessly'

This launch mode uses a mechanism very similar to Java Web Start, except that it can run without using a GUI—making it convenient to execute as a daemon on UNIX systems. To do this, you should configure this slave to be a JNLP slave by downloading *slave.jar*, and then from the slave, run the following command:

```
java -jar slave.jar -jnlpUri \
http://masterserver:PORT/computer/slave-
name/slave-agent.jnlp
```

The *slave.jar* file is downloaded from the above-mentioned URL. Make sure to replace *slave-name* with the name of the slave set-up in the master.

Tips: By default, Hudson runs on port 8080. It can be installed and managed without the need for super user privileges.

Launching a slave agent using your own scripts

If the above modes are not flexible, you can even write your own script

to launch a slave agent. The script is placed in the master computer and Hudson runs this script whenever it should connect to the slave. The script may use a remote log-in program like SSH or RSH to establish a connection between the master and slave.

The script would execute the slave agent program like `java -jar slave.jar`. The STDIN and STDOUT for the script should be connected to the master. For example, the script that executes `ssh myslave java -jar ~/bin/slave.jar` from the master Web interface would satisfy this need. For precisely this reason, running this script manually from the command line does no good.

Launching a slave agent using this mode requires an additional set-up on the slave. The benefit is that when the connection goes bad, you can use the Hudson Web interface to re-establish the connection.

Note: You should update *slave.jar* every time the Hudson system is upgraded. Though, in practice, *slave.jar* is not changed frequently.

Launching slave agents on Windows machines as a service is out of the scope of this article.

Hopefully, the above discussion has intrigued you enough to make you configure a simple Hudson job that performs certain tasks that are specific to a build and a test. Once you start using it, you will definitely be interested in its scope to execute distributed builds. **END**
