

This includes an open source BI framework as a solution accelerator, which prevents a solution from going through multiple iterations. And the levels of excellence are only escalating. “We are currently exploring the possibility of working on an R&D project on open source storage management technology,” says Banerjee.

Going beyond work

Further, a career in open source allows developers the chance to grow beyond work limitations—to get involved in the community and make a difference through their contribution. Aspire, for instance, encourages employees to participate in community projects. “Our developers have done some core improvements to a rapid development PHP framework called CakePHP. They have also contributed bug fixes, etc, to the Joomla community,” says Muralidharan.

GlobalLogic, too, encourages its developers to write code for various open source projects. “Our developers have developed the Chrysalis framework, which is a Java based J2EE framework for enterprise-ready Java platforms. This is, as of now, available off-the-shelf to our partners but we hope to contribute it to the community soon. We also have developed the EntlibAOP framework built on .NET technology that we have donated to the Codeplex community. It is still in beta shape and we plan to do more work in the area,” says Gupta. Similarly, the developers at Sonata have contributed to the open source community to enhance some products. http://sourceforge.net/forum/forum.php?forum_id=562672 is one such example where Sonata developers added custom reporting, which was needed for an open source requirement management tool (OSRMT),

“The currently available technically trained workforce meets only one-third of the demand for Linux professionals; thus, the future is bright for open source enthusiasts.”
