

Ride on Hadoop with HBase

HBase is a NoSQL database, which is similar in concept to Google's Bigtable. A sub-project of the Apache Hadoop project, it is coded in Java and layered over HDFS (Hadoop file-system). It is column-oriented, semi-structured, tolerant to hardware failure, and provides high consistency. This article compares it to conventional RDBMS systems, and talks about using HBase via CLI and Java.

Are you a developer thinking of making a Web application that could serve millions of requests per second without exponentially raising maintenance costs—and still have minimal performance issues? Such applications require high scalability, and are often hosted on

distributed networks and in the cloud. Using a conventional RDBMS like MySQL or Oracle for such applications not only has performance issues, but can also raise costs (for proprietary software licences), or suffer collapses when row counts exceed a couple of million. Also, implementing distributed, reliable, storage-
