

Vala and Genie

A Programmer's Dream Come True

Every programmer desires maximum code performance with a minimal programming effort. Performance is usually measured against the execution speed of compiled languages like C and C++, while programming effort is measured against the ease and flexibility of scripting languages like Python and Ruby. This article explores how developers can be highly productive while achieving a very high performance, by using the Vala and Genie programming languages.

When programming in compiled languages, the performance and the level of control achieved are very high, but the effort that goes into the process is also very high. With scripting languages, the ease, flexibility and productivity are very high, but not the performance. Also, in case of managed languages like C# and Java, the overhead and bloat of their virtual machines

hamper performance.

There are solutions to counter these disadvantages for both compiled and scripting languages, but those solutions are mostly add-ons, or alternative forms of the compiled and scripting languages. No single add-on or alternative offers a complete solution to a programmer's need for performance with productivity.
