DDMS

The Dalvik Debug Monitoring Service is a debugger tool that lets you debug an application running on the Android device, remotely, which is your development machine. To launch it, run `ddms`. Figure 7 shows what the DDMS screen looks like.

When the debugger launches, it automatically attaches to running emulator instances/devices. You can view the processes running on each instance in the left pane. The right pane has tabs to monitor process and emulator properties. You can see the memory usage of each of the applications running

on the emulator, and also see the CPU load, etc, on the *SysInfo* tab (see Figure 8). You can even test an application's handling of incoming phone calls by simulating a call to the emulator instance, by entering the 'calling' phone number in the 'Incoming Number' field on the *Emulator Control* tab. Figure 9 is a screen capture of the emulator, showing the result of this action.

We can also view the heap status of the device, by causing garbage collection on the device, with the following steps:

1. Select a process from the left pane.
