

provided by Django ORM library. It is recommended that business logic should be written in models so that it remains intact with models and can be used by any other app of your Django project.

- **views.py:** This is the place where you render HTML pages for the HTTP requests that are redirected to particular view function via `urls.py`. Basically, `views` contains functions, each of which get the HTTP request as first parameter. They get data from models and render HTML pages using Templates, or redirect to another view function.
- **tests.py:** This is the place for your test cases. These are functions performing unit test cases. This file should be effectively used for regression testing (to check the side effects of your code changes).

The flow of an HTTP request

To explain the flow of an HTTP request through a Django Web application, let us look at my personal website, <http://akshaydeo.me>. As Figure 2 shows, the HTTP request is sent to the Web application's `urls.py`, where URL-regular expressions are sequentially applied to it; the first match is accepted, and the request is forwarded to the corresponding view. In `views.py`, that particular function performs the required processing, which might include communication with models in the database; then, the HTML template is rendered, and the

output returned to the browser as the result of the request.

Before concluding this article, I would like to mention one site whose valuation has shocked everyone—Instagram, which was developed in Django. Instagram was one heavily used site, and each transaction had to be processed in real time. But the power of Django, and Instagram's engineering talent, made everything possible. So keep coding, and start using Django!
