and TrueCrypt will now test the boot environment and password (Figure 7). After a successful pre-test, the actual encryption begins when you hit **Encrypt**, and is seen in Figure 8.

That completes our encryption! Simple, isn't it? Now enjoy the high-end data protection from humans. But how about protection from malware? That's what the next section will guide you through.

Protecting your system

Instead of paying money to proprietary anti-malware companies, a pretty decent piece of software called ClamWin Antivirus is a great way to satiate your open source appetite. It does not provide real-time scanning out-of-the-box, but an independent add-on called Clam Sentinel gives you that functionality. You can set up ClamWin and Clam Sentinel as follows.

Download ClamWin from the link given at the end of this article. Install it by running the set-up file. While installing, you will be asked to download the latest virus definitions. Once the install is complete, you will notice the system tray

icon of the running AV. Now, install Clam Sentinel.

Download Clam Sentinel (the link is given below) and run the set-up file. Upon completion of the set-up, which is straightforward, you will be asked which disks you would like to monitor. Select the ones that are always attached to your system—these will usually be only the partitions of your local hard disks. That's it; you will now see Clam Sentinel also sitting in the system tray, providing real-time protection using ClamWin!

Today, software for almost all our computing purposes comes in an open source flavour—even for Windows. The good bit is that even if you love Windows, or are using it because you need to for some reason, there will always be open source software out there to give you the opportunity to experience the open source philosophy! **END**
