

Anuj Kumar, general manager, Red Hat India

"We try to source the best talent and the beauty with the open source development model is that talent is pretty much everywhere. We don't have to move people out of geographies to work in certain R&D centres just because we open a facility and then need to fill it up."

Q Was it as natural as this or was there any particular strategy behind it?

Anuj: Yes, there is obviously a strategy around it, which is to continue to expand Red Hat support and services in engineering. Like I said, these two Indian centres are a part of our global network of centres. It's not that we are servicing only the India geographies. The way Red Hat expands is, where we find good talent, we expand in those geographies. If we find good talent in India to help us in support and in developing certain parts of our tools, we will expand in India. We got good talent for storage when we made an acquisition. We have done similar things in Boston and Brno. So that is broadly how we decide on where and which geography to look at for any expansion or acquisition.

Q So does that mean India is now on par with nations like US in terms of the talent Red Hat is looking for?

Anuj: At Red Hat, it's not that we compare the talent in the

US with that of India. We try to source the best talent and the beauty with the open source development model is that talent is pretty much everywhere. We don't have to move people out of geographies to work in certain R&D centres just because we open a facility and then need to fill it up. We actually go to the places where we see brighter and brighter talent, if possible. In this scenario, open source development resulted in having a set of people and processes that we find extremely useful here, so we have expanded here.

Q What kind of R&D initiatives will we see in the two new R&D centres in India?

Anuj: The Pune centre is a little bit more weighted towards support tools, products and front line support, as well as engineering around Red Hat Enterprise Linux. That's Red Hat's bread and butter business. There are plenty of parts within the operating system that we do out of the Pune facility. For Bengaluru, it is primarily storage. That's the centre for engineering for the storage business.

Q So what can we expect in Red Hat Enterprise Linux 6.3?

Anuj: I think RHEL 6 has been a major release and the biggest shift in this version has been around virtualisation and embedding virtualisation full line and centre, as a part of RHEL 6. What we have done is essentially moved the scalability chart within RHEL 6 to ensure that you can increase the memory to several gigabytes, giving a lot more scalability around IO as well as across the portfolio of the hardware. So you can actually take a lot more density in terms of the virtualisation. The amount of virtual machines that you could actually run on top of RHEL 6 with the latest firmware and hardware is about four to six times more than before. When people ask me what is in the next edition of RHEL, I tell them to look at the current version of Fedora.

Q Does that mean you have increased the virtual CPUs too?

Anuj: Yes.

Q What other kinds of features can we expect to see in future releases of Red Hat?

Paul: We are working on RHEL 7 right now. We would want to focus on more connectivity in the Windows world with RHEL 7. There are two operating systems in the data centre right now--RHEL and Windows. What we can ask for is more connectivity with an active directory. What you will see is more interaction with the Windows world as we take market share from Windows. In the past, it was UNIX-to-Linux migration as people going in for new projects opted for Linux instead of Windows. But now we are actually taking market share from Windows.

Another thing that you will see is more features, more high performing and more manageable guest operating systems in a virtualised environment. You will see tighter integration, and more security features around the guest to make it a more secure, better performing and more manageable guest operating system. You will also see RHEL as a part of other platform-as-
