

Raven

A Surgical Robot Powered by Linux!

Currently undergoing tests at six different locations, this amazing robot is being developed for surgeries without human intervention!

If I were to tell you that soon enough, robots will be assisting doctors in heart surgery, you'll probably think I've watched too many Hollywood movies. However, this is indeed true. So let me introduce you to Raven, a surgical robot that runs on Linux.

Generally, no matter how good, experienced, and talented the surgeon is, heart surgery (or any other major surgery, for that matter) is a complex and risky procedure. To tackle this, researchers at the Universities of Washington and California have collaborated to develop a surgical robot named Raven.

What is it?

To begin with, Raven was initially developed for military use. However, it is already being tested for general surgical usage (*tested, but not yet approved*). Currently, it comes with two surgical robotic arms, a video camera, and an interface with which surgeons can control it. Such functionality makes it ideal for tele-surgery. Raven is not a new concept—it has been
