

is not what the programmer intended. This results in a subtle bug. There is no 'universal English', and hence it is impossible to give variable names that are universally acceptable. Further, what is considered 'correct' spelling depends on where you live, and who your target audience is. For example, I follow American English and my copy editor (who does an excellent job of making editorial improvements to my article every month) corrects my *Joy of Programming* articles and makes changes to consistently use British (or Indian) English spelling instead. This is the right thing to do, because *LFY* readers are mainly from India. However, for code, there are no national boundaries. So, what the 'right spelling' is (even within the same dialect of English) is not clear. In other words, there are no simple answers to certain types of 'naming bugs'; consistent usage is perhaps the only acceptable solution.

Sometimes, writing variable names and comments in languages other than English can render the

code unreadable. Unicode has become popular and programming languages have also adopted it. So, programmers can now write comments and variable names using their native language. Looks like a great idea, right? Except, of course, if you have to read the code, and you don't know that language! In my experience, while working with software developed in Germany, I had a tough time trying to figure out what the code was doing—because, except for the language keywords, all the code was in German! So, the code would compile perfectly and execute flawlessly but I couldn't touch the code, let alone change it, because I had no clue what the source code meant!

The author works for Siemens (Corporate Research & Technologies), Bengaluru. You can reach him at sgganesh@gmail.com.

(Continued from Page 57....)

```
<xsl:template match="xhtml:div[@id = 'header']">
<!-- remove header from the flow altogether -->
</xsl:template>
<xsl:template match="xhtml:p[@id = 'breadcrumb']">
<!-- remove breadcrumb from the flow altogether -->
</xsl:template>
<xsl:template match="xhtml:ul[@class = 'navigation']">
<!-- remove navigation from the flow altogether -->
</xsl:template>
```

You can select an HTML tag, e.g., a div, a paragraph, or a list, and narrow them by matching, say, the id or class. As you can see, it is pretty simple to skip any blocks in the original that are not a part of the core content. This matching has to be targeted at your specific site. Understandably, if you include all the blocks, the resulting site will show it all as a part of the main content, and it will be a mess.

Finally, why did the default template skip the header element, which is probably what you want to do as well? The reason is that the header is likely to be the title of your page. You may now look at the 'get-title' template in the XSL file; it is pretty readable:

```
<xsl:template name="get-title">
<!-- Returns the H1, or if unavailable, the <title> -->
<xsl:choose>
  <xsl:when test="//xhtml:h1">
    <xsl:value-of select="normalize-space(//xhtml:h1)" />
```

```
</xsl:when>
<xsl:otherwise>
  <xsl:value-of select="normalize-space(//xhtml:title)" />
</xsl:otherwise>
</xsl:choose>
</xsl:template>
```

If an H1 element is present, the *title* of the page is set to the text content associated with that. If not, it sets the title to the text associated with the title tag in the header. It is possible that your site may have the site header as the H1 element. In that case, you may need to suitably modify the *get-title* template. Looking at the code above, this should not be hard to do.

Ideally, you should design the site afresh. However, websites are now a critical resource for an organisation. Time is a luxury. 'Good enough', and not perfection, has to be your goal. There is a very high likelihood that by using *Import HTML*, you can obtain a 'good enough' site in a very short time, which makes it a module well worth exploring.
