

Archipel Virtualisation with the Goodness of XMPP

Would you like to connect your virtualisation infrastructure with your IM client? Is getting remote access to your Virtual Machines (VMs) from anywhere crucial to you? Do you need fine grained permissions management for your team of administrators? If you said “Yes” to all of that, Archipel is a must for you!

Archipel is one of those wonderful open source products that mix technologies in such an innovative way that it puts even the biggest players to shame. Yes, who knew you could build a virtualisation solution with an XMPP server? Well, Archipel has just done that and in such a beautiful way! All components here communicate with each other through XMPP messages and this allows push notifications for any events that occur in the VMs. What’s more, you can even say “Hi” to your VMs over chat and ask them how they are doing. Now that is something everyone should be looking forward to! Archipel is made to be compatible with almost every hypervisor including KVM, OpenVZ, Sun’s VirtualBox, Xen and VMware. As of now, it

only supports KVM/QEMU virtualisation, though according to its website, “Support for Xen is coming soon.”

The architecture

Archipel is basically made up of three components, i.e., the Archipel client, the Archipel agent and the XMPP server. The XMPP server is something that resides between all the components and allows them to communicate with each other. At present, Archipel recommends using only eJabberd or Openfire for XMPP communication, though you might want to try out others on your own. Each Virtual Machine has its own individual XMPP connection and list of contacts that can be communicated from anywhere using XMPP. Imagine shutting
