

LynuxWorks demonstrates end-to-end multi-level secure thin client system

LynuxWorks Inc, a world leader in the secure virtualisation market, recently said that it is demonstrating a security solution at the Information Assurance Expo, which provides concurrent user access to three isolated thin client sessions running on a single SINA Multi-level Workstation.

This collaborative high security product was first announced at the RSA conference in February this year, and is the first public demonstration of a full system, including the back-end infrastructure and configuration management components. This solution can be used by government agencies and Department of Defence (DoD) programmes that require the secure separation of multiple networks on a single workstation, or by any enterprise with highly sensitive information that needs isolation from malicious computing environments.

The SINA Multi-level Workstation (MLW) is a multi-domain thin client access solution running on a standard off-the-shelf laptop. It offers unprecedented security on a low-cost platform, providing access to multiple security domains from a single user workstation over a single network infrastructure.

The SINA MLW takes full advantage of the security benefits offered by LynxSecure, which provides a foundation to host a minimal component-based architecture with formally verified security components. The SINA MLW features multiple, isolated, bare-metal cryptographic engines for each security domain to maintain the confidentiality, integrity and authenticity of information processed in each security domain. The SINA crypto engines utilise LynxSecure's platform resource control capabilities to mitigate some of the most advanced threats posed on today's multi-level solutions running on shared computing resources, such as crypto side-channel attacks and covert user data spill channels.

The demonstration at the IA Expo is a debut for the back-end SINA network gateways. The SINA gateway is a single level cryptographic network gateway that connects the SINA MLW user sessions to clear-text security domain infrastructures. The SINA gateways support redundant link protocols to provide hardware failover protection and link teaming that combines Ethernet ports to increase link throughput.

The SINA product line utilises an ingenious smart card management system, where all SINA configuration parameters and security credentials reside on smart cards instead of the hardware platforms. This provides a transparent hardware configuration model, allowing SINA products to be easily replaced and upgraded by simply swapping out the hardware components and reinserting the existing smart cards.

Disabled students at DU to be given tablets!

There is a tablet for everyone!

The use of these multifunctional devices is picking up fast in the educational sector and, recently, many tablet makers have forayed into this segment with special applications designed for students. It is being reported that Delhi University (DU) will be giving out tablets to its disabled students.

Every year, 3 per cent of the seats in DU are reserved for disabled students; the university will now be providing them with tablets to aid them in their studies. As per the TOI report, the tablets will be pre-installed with software that will help them with their subjects and lectures. For blind students, the tablet will be well equipped with audio books and lectures, and for deaf students the tablet will have speech-to-text translation incorporated. Vipin Tewari, deputy dean, Students' Welfare, said, "This is the first time that the varsity has taken such pro-active measures."

About 1,600 students fall in the disabled students' category in DU, and all of them are expected to be given the tablet by the end of this year. It has not been revealed which tablet maker DU will tie up with or whether the tablets will run Android or not.
