

Figure 3: New Relic application monitoring and management

Figure 4: XWiki in CloudBees

Papertrail—logging

CloudBees' management console provides access to the server's unrefined log file. Papertrail provides aggregation and analysis of log files—it can be used to aggregate, tail and search log messages from applications deployed on the CloudBees platform. Papertrail automatically collects and reports the log data from running CloudBees applications. It needs to be enabled from the CloudBees dashboard for specific applications. It combines logs from different sources, keeps them for longer periods of time, and provides summary analysis based on the logs. It saves useful searches, enables team-wide visibility, notifies external services of important events, automatically archives logs, and gives access to log details via the Web, the command-line and the API.

New Relic—deep monitoring and management of Web apps

New Relic is an application performance monitoring service. It embeds its software agent into your application to collect detailed performance information about your application in real time. New Relic monitoring is part of the CloudBees ecosystem, so you can turn it on for any of your applications with a few clicks. In CloudBees, the New Relic software agent is automatically instrumented into your application at the time of deployment, without the developer needing to change any source code.

New Relic monitors app performance at the component level, and spots potential bottlenecks. It determines if performance issues are in the front end, the app, the database, or at the network level. It is the tool developers need to monitor real user experiences, proactively identify application bottlenecks,

and ensure superior online service delivery.

XWiki

XWiki Cloud is a cloud-based wiki that is secure, simple to use and easy to organise. It is a light and powerful development platform. Using structured data and in-page scripting, you can create macros and applications that extend the capabilities of your wiki and customise it to match your specific needs. With XWiki, CloudBees provides easy content creation for applications, importing Office documents (.doc, .xls, .ppt, etc) to your wiki, and a powerful search engine to search in every element of your wiki, including attachments.

The SendGrid service

CloudBees now supports sending mail from applications with the SendGrid Service for RUN@cloud. SendGrid offers a hosted SMTP service to send emails to either a mailing list or to individual users. Once it is enabled, it is available as a JNDI resource in your CloudBees application.

SendGrid's cloud-based email infrastructure relieves businesses of the cost and complexity of developing and maintaining custom email systems. It provides reliable delivery, scalability and real-time analytics, along with flexible APIs that make custom integration a breeze. SendGrid solves the technical challenges, eliminating your email headaches, so that you can focus on your core product and meet the email demands of your business.

In the next article in this series, we will look at how to deploy a JEE application on CloudBees, how to run it on the local and cloud environment, and how to configure a CloudBees plug-in in Eclipse.
