

Georges at Indiana University and the US Navy came up with this amazing malware. It uses a smartphone's camera, gyroscope and accelerometer to create a 3D model of the target's premises. This model can then be used to extract financial and personal information. Interested readers can visit <http://goo.gl/hdGpD> to download the research paper published on this project.

"So how can I protect my device?"

A new malware is unleashed on Android users every minute. It's like that famous dialogue from the movie Spiderman (with slight modifications), 'With great popularity come great threats'. It was true for Microsoft Windows, and it's now true for Android. So what can you do to protect your device from all these lurking dangers? A few precautionary measures are listed below:

- Always use the Google Play Store to download apps (chances of catching an infection are less here).
- Even if you're downloading from unofficial stores, verify the authenticity of the publisher and the app by Googling about them. (At least you'll make an informed decision.)
- Install a mobile anti-virus. All the good options are available in Google Play Store – Norton, Kaspersky, McAfee, BitDefender, etc.
- If you come across a rogue app, or your device gets

infected by a malware, make sure you report it (it won't help your case, but might save many others).

- I'd advise against rooting your device, but even if you are doing it, verify the credibility of the ROM developer.
- Turn off your device's Wi-Fi, Bluetooth, GPS, NFC, etc, when not required (it will save your phone from being hijacked).

Going by the current reports and predictions of all leading security researchers, the year 2013 isn't going to be an easy one for Android users. eSecurity Planet predicts that Android malware infection will rise to 18 million by the end of this year. BitDefender has dubbed 2013 as 'the year of mobile malware' for Android. Given the popularity of the Android platform, these predictions might actually come true. If for any reason you're having second thoughts about Android after reading this article, please note that it was written to increase awareness about these malware, since 'knowing what you're getting into' helps.

not mean that the routers translate IPv4 addresses into IPv6 or vice versa. It only means that the equipment can connect to independent IPv4 and IPv6 networks simultaneously. An important consideration is that the amount of work done by dual-stack routers increases substantially. Therefore, higher performance equipment should be specified to ensure it can keep up with the combined workload of IPv4 and IPv6 traffic."

Tunnelling

This is yet another process that enables companies to become IPv6 ready without much effort. According to a white paper from Brocade Communications, "Tunnelling allows an 'envelope' using one address type to be put inside another that uses a different address type. For example, an envelope using IPv6 addresses can be put inside an envelope that uses IPv4. This envelope can then be routed over an existing IPv4 network. At the destination router, the outside IPv4 envelope is discarded, and the IPv6 envelope is used to forward the electronic information to an IPv6 device. This can also work the other way, by putting IPv4 envelopes inside IPv6 envelopes. Although tunnelling can be used to move incompatible envelopes across dissimilar networks, this approach complicates network design and management,

and can create unexpected security holes, so it has to be carefully designed."

Network Address Translation (NAT)

This method involves address translation between the IPv4 and IPv6 address types. This is a method worth trying because not many Web applications and IP telephone signalling protocols support IPv6 addresses, as of now. Unnikrishnan says, "Companies that leverage the Internet heavily, or have a large investment in IP telephone systems, will need to maintain the IPv4 information used by these applications and devices to ensure that existing monitoring and management tools do not break. Investing in NAT at the application layer, instead of just a dual-stack router, preserves the substantial investment in monitoring, business intelligence and management tools that many applications use, and which companies depend on for their competitive advantage. With NAT, they can communicate with customers and suppliers, regardless of which IP protocol is used, and can better manage the cost and risk of rebuilding a large part of their business applications and existing IPv4 networks."
