

Boost your MySQL Performance with Cloud Computing

Thousands of new online and mobile applications are launched every day, yet the success of these applications is dependent on uninterrupted access and availability. As mobile computing adoption grows, so does the amount of data – causing most successful companies to eventually hit a (database) wall. The result: poor performance and frustrated customers.

The ideal solution for such scenarios would be either purchasing a proprietary database or investing heavily in purchasing new hardware. Most companies can't, and shouldn't have to, install new databases every time they grow.

This is where eNlight's cloud offers the perfect solution. The eNlight cloud from ESDS cloud eliminates complexity from organisational applications and database infrastructures by enabling a fast and efficient response to dynamic business requirements. The eNlight cloud provides real time elasticity that increases database availability without requiring any changes to the existing infrastructure.

Making LAMP a Cloud

MySQL doesn't scale on its own. MySQL needs four fundamental resources to do its work: CPU cycles, memory, I/O, and the network. Installing MySQL on a cloud-hosted server isn't the only way of using MySQL in the cloud. It is more important to satisfy the resource needs of the database server.....

Just-in-Time Resources!

eNlight is a one of its kind solution and is the first in the industry to provide automatic scalable services. eNlight, with its iNtelligent technology, senses the need for additional resources and also when to withdraw them, thus ensuring top notch performance at optimal prices.

One does not have to worry about resource allocation and server upgrade/downgrade cycles as eNlight will take care of all these factors and adjust the resources in realtime, automatically, without having to reboot or even a pause in the server. eNlight is the solution to resource related problems faced on servers. The resources are monitored continuously; so whenever a load is detected on the virtual server, the cloud allocates more resources to that server. The main advantage of this feature is – the quantum of resources stays proportional to the user's requirements.

Users do not have to invest in procuring the right amount of hardware, thus saving almost 60 per cent of their hardware costs.

Advantages of scaling up or down

- It's simple – This type of scale is usually fairly simple to deploy, and is supported by most of the databases used today (so that when more processors and cores are identified, the database

software is able to take advantage of the additional resources).

- No code changes to the application – it still runs against a single (larger) machine.
- Scales both throughput and capacity

Another way to optimise the database is sharing on the cloud. This can be done by selecting a key in the data and splitting the data by hashing that key and having some distribution logic. It can also be done by identifying the application needs and setting different tables or different data sets in different databases.

Benefits with the cloud

- This approach scales both throughput and capacity.
- This solution scales both reads and writes.
- Scaling is done online with no downtime/partitioning event. New resources are added/removed automatically, on the fly, in a way that's transparent to the application.
- Scales beyond the limitations of any single machine/node.
- No application change is needed.

Use Your Memory

RAID 10 mirroring and striping is possible, with as many disks as you can fit in your server or raid cabinet. A database does a lot of disk I/O even if you have enough memory to hold the entire database. Why? Sorting requires rearranging rows, as does 'group by', 'joins', and so forth. Plus the transaction log is disk I/O as well!

Fault tolerant and redundant

eNlight, the latest and most prominent entrant in the cloud hosting market, addresses all your concerns around optimising operating costs, managing perfect resource utilisation, issues involved in the upgrade or downgrade of hardware, coverage in case of disaster, ease of provisioning and management, ease of back-ups, data security, etc. eNlight also ensures that you are doing your bit in maintaining a balance between taking care of your IT infrastructure as well as the earth.

All ever-changing demands of IT infrastructure are taken care of by eNlight, allowing you to focus on your business and grow your revenues, with eNlight providing a helping hand in saving you some expenses, resulting in an indirect addition to your revenues!

There is no such thing as 'better hardware'; but the hardware that serves the application needs to be better. Database operations such as back-up and large-scale queries are now much more efficient, thanks to eNlight cloud, which has the ability to handle increasing IOPS.
