

For instance, when a service sends a request to another, Gofr checks whether the service and its database are operational, and the connection is functional. It then ensures the request is processed as intended. If something goes wrong, Gofr halts retry attempts until the issue is fixed, preventing unnecessary errors.

Q. Can Gofr do the same in dynamic environments?

A. Yes, Gofr can propagate updates across multiple microservices effortlessly. If an issue arises, updating the Gofr framework version can resolve the problem across all connected services without requiring additional manual effort. It offers real-time visibility into request flows and provides tools for making instant changes to metrics and logs. These updates can even be done in live production systems, saving significant time and effort by eliminating the need to restart applications. Developers can see how requests flow through the entire microservices architecture. This real-time insight into metrics and logs ensures that any issues are identified and resolved quickly. This capability is especially important for production-grade systems, where uptime and performance are critical.

Q. What kind of advantages does Gofr.dev offer to developers?

A. Gofr.dev offers numerous advantages, even for those who are not Go developers. It is incredibly fast, offers unmatched observability and allows developers full control over how they want to build their applications. Even someone who is not a programmer can look at the code and understand what is happening.

Features like tracing, logging, and metrics are built into the framework as a standard, not added as an afterthought. This unified approach ensures that logs and metrics from all databases

Gofr.dev is an open source framework purpose-built for microservices. It has observability, dependency management, and other essential features integrated into its core.

ZopDev is a cloud-neutral cloud management tool that simplifies managing cloud deployments, whether it's a single application, multiple applications, or hundreds of microservices across various clouds. It provides a unified interface to manage deployments, configurations, and operations while enabling seamless migration to any cloud, unified observability, and cost management.

For instance, a developer can continue using Gofr.dev within AWS, as they always have, without involving ZopDev. However, if the organisation decides to optimise costs, or gain centralised visibility into its cloud operations, ZopDev steps in as the unified platform that simplifies these operations.

Aryan Mehrotra,
Software Developer at zop.dev

and services are readily available. This stems from the fact that Gofr.dev was initially designed for enterprise-level applications. Its enterprise-grade standards are baked into the framework rather than bolted on later. This makes Gofr.dev not just a development tool but a comprehensive solution for building and managing robust applications.

Q. Is the open sourcing of Gofr.dev an effort to encourage more developers to use Go as a programming language?

A. Yes, that is certainly one of our goals. Go is a fantastic language, but it does not receive the widespread

recognition it deserves. By creating and open sourcing Gofr.dev, we aim to demonstrate Go's potential and encourage its adoption among a broader audience. Our ambition is to make Gofr.dev the *de facto* framework for Golang-based microservices.

Open sourcing is not a small task and definitely not just about making the code publicly available. It involves more than just uploading the code to GitHub. It requires continuous effort to ensure that the framework remains relevant, usable, and widely adopted. Gofr.dev is our way of propagating the benefits of Go and helping the language reach its full potential.

Q. How do you plan to make Gofr.dev the 'de facto standard'?

A. When we say 'de facto standard', we do not mean through certifications or formal endorsements but rather by becoming the natural choice for developers. Achieving this goal requires staying grounded, listening to the community, and being highly responsive to their needs.

One of our upcoming initiatives is to release templates for common use cases. Today, Gofr.dev allows you to build any application from scratch. However, we aim to make life even easier by providing ready-to-use templates for SaaS applications such
