

Table 1: A comparison of different AI systems

	Agentic AI 	Generative AI 	Traditional ML 
Concept	Agentic AI systems operate autonomously, make decisions, and adapt to their environment based on predefined goals.	Generative AI systems are designed to create new content—text, images, or other forms—by learning from existing data.	Traditional ML involves systems that analyse data to recognise patterns and predict or classify outcomes based on past data.
Primary functionality	Autonomous decision-making and task execution without human oversight.	Creation of novel and realistic content by understanding data patterns (e.g., generating text, images, etc).	Recognition of patterns and making predictions or decisions from historical data through models.
Illustrative examples	Autonomous systems in marketing, intelligent agents in business processes, or self-driving cars.	GPT-4 for text creation, DALL-E for image generation, AI tools for creating art.	Fraud detection models, decision trees, neural networks used in applications like recommendation systems.
Objective	The aim is to autonomously address problems and take actions based on goals, adjusting as necessary to changing conditions.	The focus is on generating authentic, realistic outputs by mimicking patterns learned from the data.	The goal is to uncover patterns from data and provide accurate predictions or classifications based on prior information.
Interaction with humans	Operates with minimal human input, focusing on independent functioning.	Can engage with or operate independently based on human input, depending on the task; often needs guidance for refinement.	Requires human input during the training phase, with periodic re-training, though it functions autonomously for making predictions.

Figure 6: Multi-agent system

same system, is equipped with large language models that allow it to focus on a certain domain such as data processing or decision-making to fulfil different goals.

Collaboration framework: There is interaction and coordination to share essential information, make decisions more impactful, and enhance work effectiveness. The framework allows agents to share information, come to a consensus, and coordinate their activities to achieve an objective. The method also ensures much of the work is done in parallel.

Scalability: Another benefit of employing an MAS is its scalability
