

away, but on scrolling down you'll find monitoring graphs for these demo services as well? This is just the tip of the iceberg, and you can access the finer details about the monitored endpoint by clicking on the **View** buttons located on the respective graphs.

Figure 1: Statping-ng setup page

You'll find a *Dashboard* link at the bottom of the status page, which takes you to another page (after entering the admin credentials already set by you in the statping-ng setup page) presenting every possible setting provided for the statping-ng configuration. Go to the *Services* tab to see and modify the demo services shown on the page. You don't need to learn anything else to make use of statping-ng as everything is driven by its highly user-friendly tab pages for different operations. Just go to its *Services* tab and try adding/removing some of the probes by selecting the appropriate drop-down items for HTTP/TCP/UDP/gRPC/Static services, ICMP Ping, and setting various other applicable values. You could also set up various notifiers to receive various online/offline alerts, post various announcements for respective services, browse through the statping-ng logs, add different kinds of users, etc.

An important feature of statping-ng is the ability to backup and restore current statping services, groups, notifiers, and other settings to and from a JSON file, respectively. The statping-ng wiki provides more detailed information about its various aspects to get the most out of this tool.

Finally, let's shift gears to start and configure the statping-ng programmatically through its configuration settings only, without any manual steps involved. *Dockerfile_MyStatpingNG* is shown below. You can create a new Docker image using the command
