

Wireshark 4.4.8 comes with updated protocol support and key bug fixes

The Wireshark team has announced the release of Wireshark 4.4.8, the eighth maintenance update in the 4.4 stable series of the world's most popular open source network protocol analyser. Available for Linux, macOS, and Windows, this update brings enhanced stability, updated protocol support, and several important bug fixes.

While the release does not introduce new protocol support, it updates the handling of several existing protocols, including ASTERIX, DLT, DNP 3.0, DOF, DTLS, ETSI CAT, Gryphon, IPsec, ISObus VT, KRB5, MBIM, RTCP, SLL, STCSIG, TETRA, UDS, and URL Encoded Form Data. The release addresses an issue where renegotiated DTLS sessions were not being decrypted properly and fixes a crash that occurred when opening packets in a new window after reloading Lua plugins, especially when certain column formatting preferences were set. It also corrects a visual glitch in packet diagrams that caused field values to be shown twice when the field type was set to FT_NONE.

The update also fixes an issue with the DNP3 timestamp functionality

failing after the Year 2038 epoch. Another significant fix addresses a hang during Wireshark's initialisation when using an Android emulator, caused by a blocked *androiddump recv()* function. A UTF-8 encoding problem and an error in parsing keys in form-urlencoded data have also been resolved.

Users can find the full changelog and release notes on the Wireshark website. Wireshark 4.4.8 is available now as a source tarball from the official download page, or it can be installed via Flatpak through Flathub.

The original GitHub Copilot extension, which handles inline code completions, remains proprietary for now. However, Microsoft plans to eventually merge its core features into the open Copilot Chat extension, unifying major AI capabilities into one open source module.

With the source code now available, Microsoft is encouraging developers to explore, contribute, and share feedback. The GitHub repository includes detailed documentation and a comprehensive FAQ to help contributors navigate the project.

Intel shuts down Clear Linux project

Intel has officially discontinued its high-performance Clear Linux distribution. Over the past decade, Clear Linux consistently demonstrated what's achievable with optimised out-of-the-box performance on x86_64 systems—not just on Intel hardware but also delivering impressive results on AMD platforms. However, amid ongoing cost-cutting measures, Intel has now decided to sunset the project.

Intel released the following statement confirming the shutdown: “After years of innovation and community collaboration, we’re ending support for Clear Linux OS. Effective immediately, Intel will no longer provide security patches, updates, or maintenance for Clear Linux OS, and the Clear Linux OS GitHub repository will be archived in read-only mode. So, if you’re currently using Clear Linux OS, we strongly recommend planning your migration to another actively maintained Linux distribution as soon as possible to ensure ongoing security and stability.

“Rest assured that Intel remains deeply invested in the Linux ecosystem, actively supporting and contributing to various open source projects and Linux distributions to enable and optimise for Intel hardware.

“A heartfelt thank you to every developer, user, and contributor who helped shape Clear Linux OS over the last 10 years. Your feedback and contributions have been invaluable.”

The news, though not entirely unexpected, is still disheartening. There had been prior speculation about Clear Linux being at risk, particularly as Intel shifted focus towards contributing more performance enhancements upstream and supporting broader Linux distribution compatibility.

Clear Linux brought forward several noteworthy innovations, including advanced packaging techniques using profile-guided and link-time optimisations, custom kernel tuning, and other performance-boosting features. Fortunately, some of these enhancements have been adopted by alternative distributions like CachyOS. Intel engineers are also continuing their collaboration with other major Linux distros to improve performance—though the extent and direction of these efforts remain uncertain.
