

Shape the Success of Your Business with Smart Data Management and Security Practices

In today's world, data is a company's best asset, if used well. Also, data management and data security are no longer merely good business practices – they are critical to the success of an organisation.

Governments around the world are trying to protect user data with the help of legislation. In India, the Digital Personal Data Protection Act (DPDP) has added an additional compliance burden on businesses. Similar legislation, such as the GDPR in Europe and the CCPA in California, is being complied with around the world.

How open source powers data management and security

Open source software is driving the silent but vast transformation in data management and security, as it gives end users transparency, flexibility, and innovation at scale.

An open source model enables an organisation to audit the code, check security protocols, and confirm compliance without having to rely on a black-box system, thus ensuring transparency. Trust is of paramount

We are in the age of data. Information is now a business's most important asset; every click, every transaction, every sensor signal, every customer interaction, when captured and managed well, can turn into data. If we harness this data well, we can extract substantial insights to drive better business decisions. Data that is poorly managed can lead to inefficiency, lost opportunities and incorrect decision-making. Data that is not secure can lead to security breaches resulting in reputational damage, regulatory penalties and reduced customer confidence.

The urgency around data management and security has never been higher. IDC predicts that by 2025, the world will generate more than 175 zettabytes of data. Companies today are required to manage overwhelming amounts of structured and unstructured data, often in real time. Without good management systems this data can become a liability instead of an asset.

Reports of security breaches and cyber attacks continue to rise across all sectors. In India, there have been 2000+ cases of data theft reported in 2023, let alone the cases that were not reported. The average cost of a data breach globally is \$4.45 million, according to IBM.
