

DuckDB: The High-Performance Database for Data Analytics

Database applications are integrated in almost every software project, be it a desktop application or cloud-based deployment. Database servers help the frontend graphical user interface (GUI) interact with the data for multiple operations like inserting, deleting, and updating records on-demand for effectively deploying software applications.

High performance and fast-track data analytics is required in e-governance, social and corporate applications. Different categories of databases are used for this. These include relational databases, object-oriented databases, time series databases, etc (Table 1).

NoSQL databases (Table 2) are generally used for unstructured data including social media platforms on which different formats of data are streamed at huge speeds. Data on social media includes images, videos, multimedia
