

Eclipse Foundation releases Jakarta EE 11

Jakarta EE 11, announced by the Eclipse Foundation’s Jakarta EE Working Group, marks a transformative release of the enterprise Java platform. Building on its Web and Core Profile predecessors, this version embraces cloud-native demands with smarter testing, modern APIs, and enhanced Java 21 support. Key innovations include the debut of Jakarta Data—a new specification designed to simplify data access with intuitive repositories, pagination features, and a lightweight query language. The release also deprecates outdated components like Managed Beans in favour of a streamlined CDI-first approach and offers broader support for Java Records and Virtual Threads.

Upgrades like JUnit 5 and Maven-based Test Compatibility Kits (TCKs) cut down testing complexity and boost speed. Enhanced concurrency for Java 21 via Virtual Threads delivers real performance gains while aligning with modern Java features. With API stability and backward compatibility still in place, Jakarta EE 11 ensures innovation doesn’t come at the cost of reliability.

Enterprise teams gain a future-proof platform backed by open standards and a vibrant global community. Certified implementations are already live, including Eclipse GlassFish (Web Profile), Open Liberty by IBM, Red Hat’s WildFly, and others. Organisations adopting it benefit from lower technical debt, better runtime performance, and easier cloud integration—making it ideal for mission-critical systems.

The version is available now and supports Java 17+, with extended capabilities for Java 21. “Proud to co-lead Jakarta EE 11—Jakarta Data, spec updates, and cloud

VirtualBox 7.1.12 enhances Linux kernel 6.16 support

Oracle has announced the release of VirtualBox 7.1.12, the latest stable update to its popular open source and cross-platform virtualisation software, available for GNU/Linux, macOS, and Windows systems. Arriving about five weeks after version 7.1.10, this update brings a range of improvements, particularly for Linux users.

Building on the initial support introduced in the previous version, VirtualBox 7.1.12 includes further enhancements for compatibility with the upcoming Linux 6.16 kernel, both for hosts and guests. The Linux Guest Additions have been refined with fixes for multiple issues, including one that prevented VBoxClient from starting on older Linux 2.6 kernels, a udev rule error that triggered system log warnings, and an incorrect status report from `rcvboxadd status-kernel` on kernels older than Linux 3.10.

For Linux hosts, the release resolves a kernel panic related to bridged networking with interfaces managed by the `ixgbe` driver on newer kernels. Other issues addressed include virtual machines with lengthy names failing to start, and a ‘Guru Meditation’ error occurring in outer virtual machines during nested virtualisation.

Users can review the full list of changes in the official release notes and download VirtualBox 7.1.12 from the official website as a universal installer for Linux, as well as dedicated packages for distributions like Fedora, Debian, Ubuntu, openSUSE, and Oracle Linux.
