

Linus Torvalds admits using Google's AI coding tool in the AudioNoise project

Linus Torvalds, the creator of Linux and Git, has acknowledged using Google Antigravity, an AI coding tool, in an open source GitHub project called AudioNoise. The admission marks a notable moment for AI-assisted coding within the open source ecosystem, given Torvalds' long-standing influence on software engineering practices.

Torvalds confirmed that parts of AudioNoise were developed using what is popularly referred to as 'vibe coding', a workflow in which an AI model generates code directly from natural-language prompts. In particular, the Python-based audio sample visualiser included in the repository was largely produced using Google Antigravity rather than being written manually.

In the project's README, Torvalds wrote: "Also note that the python visualizer tool has been basically written by vibe-coding. I know more about analog filters, and that's not saying much, than I do about python. It started out as my typical 'google and do the monkey-see-monkey-do' kind of programming, but then I cut out the middle-man — me — and just used Google Antigravity to do the audio sample visualiser."

AudioNoise is published as an open source repository under the GPLv2 licence, underscoring that AI-generated code can coexist with established open source licensing models. The project is described as a hobbyist exploration of digital audio effects, focusing on digital signal processing and guitar pedal design.

Torvalds' candid disclosure highlights how even highly experienced developers may rely on AI tools for tasks outside their primary expertise, while reinforcing that human judgement and oversight remain essential.

Alibaba launches Qwen-Image-2512, an AI image generation model

Alibaba's Qwen AI research team has released Qwen-Image-2512, a fully open source, enterprise-grade AI image generation model positioned directly against Google's Nano Banana Pro, also known as Gemini 3 Pro Image.

Licensed under Apache 2.0, Qwen-Image-2512 allows free commercial use, modification, fine-tuning, and self-hosted deployment. The release addresses core enterprise requirements around predictable costs, deployment sovereignty, data governance, and localisation—areas where closed systems remain tightly coupled to vendor infrastructure.

The model is designed for text-heavy, structured visual generation, including infographics, slides, menus, posters, and multilingual enterprise documentation. It supports both Chinese and English prompts, with improved text accuracy and layout consistency.

In blind, human-evaluated testing on Alibaba's AI Arena, Qwen-Image-2512 ranked as the strongest open source image model and remained competitive with leading closed systems, reinforcing its positioning as production-ready.

The model is accessible via Qwen Chat, hosted demos on Hugging Face and ModelScope, and through Alibaba Cloud Model Studio as qwen-image-max.

KawaiiGPT turns cybercrime into a one-click operation

KawaiiGPT, a free and open source black-hat AI tool, is significantly lowering the barrier to cybercrime by enabling phishing, malware creation, and ransomware campaigns within minutes. By removing the need for advanced technical skills, the

tool is reshaping the traditional economics of cybercrime, shifting power from skilled attackers to virtually anyone with access.

Unlike paid underground tools such as WormGPT 4, which reportedly costs around US\$ 50 per month, KawaiiGPT is

completely free, openly available, and publicly hosted online. It can be installed on Linux systems in roughly five minutes, making high-impact cyber-attack capabilities widely accessible.

The tool automates the generation of convincing phishing emails, malicious scripts, and full ransomware workflows using AI-generated content. This transition from human-generated to machine-generated attacks increases both speed and scale. Threat researchers estimate more than 500 active users are already collaborating openly, sharing prompts, scripts, and attack ideas via Telegram groups, signalling early but organised adoption.

First identified in July 2025, KawaiiGPT quickly drew attention from cybersecurity researchers as an emerging real-world threat. Built on a transformer-based large language model, it is fine-tuned on malicious datasets including phishing templates, exploit code, and malware scripts. It operates through a lightweight command-line interface or REST API and generates code using legitimate Python libraries, allowing malicious activity to blend into normal administrative traffic.

While no major public breach has yet been directly attributed to KawaiiGPT, threat intelligence teams report its use in active campaigns targeting finance, healthcare, IT services, and small businesses.
