

platforms, agent-based automation systems, academic assistants, and research support tools for literature review and knowledge organisation.

A selected set of no-code AI tools aligned with practical academic and professional needs are reviewed below, covering four key areas: AI model training for beginners using Google Teachable Machine, task automation through AI agents, academic documentation support, and research writing assistance.

Google Teachable Machine: No-code AI for rapid learning

For many beginners, the main challenge in AI and ML is not understanding concepts but knowing how to begin. Students are often required to build a simple AI model, such as an image or gesture classification system, without prior coding experience. Traditional ML workflows involve programming, library installation, and error handling, which frequently become obstacles instead of learning opportunities.

In such student-oriented scenarios, the primary requirement is to quickly train a model, test its predictions, and understand the basic idea of classification within limited time. This challenge can be effectively addressed using Google Teachable Machine, a browser-based no-code platform designed for rapid experimentation. The platform allows students to solve three types of problems: image classification, audio classification, and pose classification. By collecting sample data through a webcam or microphone, assigning it to different classes, and training the model with a single click, students can build functional AI models within minutes. This approach enables learners to focus on conceptual understanding and practical application rather than technical complexity.

AI agents for task automation: Reducing daily workload

In academic and professional

environments, a large amount of time is spent on repetitive and rule-based tasks rather than meaningful analytical or creative work. Activities such as managing emails, updating spreadsheets, sending reminders, generating reports, and handling form submissions are performed repeatedly and manually, increasing workload and the chances of human error.

A common real-life scenario involves students or faculty members working across multiple digital platforms simultaneously. Assignment submissions, progress tracking, notifications, and periodic reporting demand constant attention, even though these tasks do not require human intelligence. This is where AI agents offer practical support by automating routine operations. AI agents are systems that observe inputs, apply predefined logic, and execute actions automatically. When implemented using no-code platforms, these agents can be created without programming knowledge and run continuously in the background.

Key capabilities of no-code AI agents are:

- Monitor events such as emails, form submissions, or file uploads
- Apply rule-based or AI-driven logic
- Perform actions like updating documents, sending notifications, or triggering workflows
- Reduce manual effort and execution delays
- Improve consistency and time efficiency

Popular no-code AI agent tools are:

- n8n
- Zapier
- Make.com
- Flowise
- Relevance AI

No-code AI for research writing and literature review

Research writing is one of the most demanding tasks in academia, particularly for students and early-stage researchers. The primary challenge is often not generating ideas but managing

a large volume of research papers. Activities such as searching literature, identifying key findings, comparing methodologies, and summarising results require significant time and effort, especially for beginners unfamiliar with systematic review practices.

A common scenario involves a student writing a review section for a project or research paper. Identifying credible sources, understanding prior contributions, and supporting arguments with evidence becomes difficult when dozens of papers must be read manually. This often results in shallow reviews or incomplete referencing.

No-code AI research assistants address this challenge by simplifying literature discovery and analysis. These tools allow users to search and analyse academic papers using natural language queries, automatically extracting structured information such as methodologies, datasets, findings, and limitations. This enables quicker comparison of studies and easier identification of research gaps, while preserving academic integrity.

Popular no-code research writing tools are:

- Elicit
- Research Rabbit

Overall, no-code AI research assistants act as productivity enhancers rather than content generators. By reducing the time spent on literature exploration and evidence collection, they allow researchers to dedicate more effort to interpretation, discussion, and contribution. This makes them valuable support tools in modern research writing workflows.

Reducing AI-generated content and improving originality

In academic writing, maintaining originality is a critical requirement for students and researchers. Although AI-assisted tools help in structuring and drafting content, the output may sometimes appear machine-generated or overly generic. As a result, plagiarism
