

Figure 4: Ethereum

Binance Smart Chain (BSC)

<https://www.binance.com>

This open source blockchain platform has been developed by Binance for building decentralised applications and digital assets. BSC provides instant compatibility with Ethereum DApps and offers fast block times and low fees. Its DeFi application is widely used for dYdX.

Cardano

<https://cardano.org/>

Cardano is an open source blockchain platform that focuses on security, scalability, and sustainability. It uses a proof-of-stake consensus algorithm known as Ouroboros and is built to be immensely energy efficient. Cardano provides decentralised smart contracts and DApps, targeting enterprise and government use cases (especially financial).

TRON

<https://tron.network/>

TRON is an open source blockchain platform mainly focused on creating decentralised content-sharing platforms. It is recognised for its high scalability and throughput capacity, lending itself to be an ideal building-block for decentralised applications around entertainment, gaming and social

media. TRON has an architecture that supports high speeds and low transaction fees, which also makes it very scalable.

Corda

<https://r3.com/get-corda/>

This open source blockchain platform is designed for enterprise use cases, including finance, healthcare and supply chain. It allows companies to interact directly with each other and do so with privacy, security and regulatory compliance. Corda is a permissioned platform that provides a distributed ledger without a native cryptocurrency, unlike other blockchain platforms.

Chainlink

<https://chain.link/>

Chainlink is an open source decentralised oracle network that facilitates smart contracts with secure access to real-world data, APIs and payment systems. It is also a key

tool for secure access to external data sources, off-chain data and APIs, making it an important platform for the development of decentralised finance (DeFi) applications and DApps requiring real-time data feeds.

NEO

<https://neo.org/>

This open source blockchain platform helps create a network of decentralised digital assets and smart contracts. NEO also features a unique, multi-language supporting mechanism, with developers able to write their decentralised applications in C#, Python and Java, and place data on top of its blockchain, similar to Ethereum. NEO is designed to support the digitisation of assets and provide automatic contract execution to build a smart economy.

For developers working to build and deploy secure decentralised applications, open source blockchain platforms are critical for security and privacy. These platforms provide comprehensive documentation, community support, and the flexibility to adapt blockchain solutions according to business or technical requirements. From high-performance platforms like Solana and Polkadot to enterprise-grade systems like Hyperledger and Corda, there are platforms for all uses, whether finance, healthcare or content generation. Developers can speed up their blockchain projects by using these open source tools, which at the same time contribute to the larger blockchain ecosystem. **END** 🐧
