

Building an IoT Product?

Use OpenRemote

OpenRemote, the open source IoT platform, helps businesses and developers innovate while lowering expenses and enabling complete control over their connected products.

Connected products now enable devices, sensors and systems to exchange information without interruption. However, this comes with challenges like high expenses, complicated system integration and restricted management capabilities of standard IoT platforms.

Organisations can create adaptable connected products through OpenRemote's open source IoT platform. This platform provides the essential tools and automation functions that help developers achieve their IoT goals.

What is OpenRemote?

The widespread implementation of connected products faces critical challenges: vendor lock-in, high integration costs, fragmented data, and privacy risks. Proprietary platforms restrict flexibility and slow down innovation by limiting interoperability

and product scalability. To address these barriers, organisations prefer open, customisable IoT platforms that preserve data sovereignty, reduce costs, and accelerate experimentation. Open source IoT ecosystems foster adaptability, transparency, and community-driven innovation, creating a sustainable path forward. Platforms like OpenRemote exemplify this approach by combining openness and scalability with strong community engagement, ensuring organisations can innovate securely and efficiently while overcoming the constraints of proprietary solutions.

OpenRemote enables businesses to speed up their innovation process while making it simpler to create connected products. Organisations have the freedom to test new concepts and merge different systems through its open architecture. This architecture

helps academic institutions, businesses and startups to join forces for platform development which results in continuous innovation.

The key components of OpenRemote are:

Device and protocol integration:

The system enables standard protocol connections for various devices through MQTT, Modbus, BACnet and REST APIs. It allows users to add new devices and legacy systems through standard interfaces, which eliminates the need for complex modifications.

Data management and dashboards:

The system enables real-time data collection and visualisation as well as analysis of information from various devices spread across different sites. It helps users create personalised dashboards, which generate valuable data insights that support organisations in their decision-making process.
