

India-based Weam opens its AI code to the world

Weam, an AI adoption platform developed in India, has transitioned to a fully open source model—making its entire codebase publicly available on GitHub. The move marks a bold shift from a subscription-based SaaS business model to a community-driven framework, positioning Weam as one of the first Indian platforms to open its enterprise AI stack to global collaboration.

The decision followed extensive consultation with enterprise clients, many of whom cited key limitations in proprietary AI platforms, such as restricted customisation, poor integration with internal systems, and lack of data sovereignty.

“Our enterprise customers made it clear that true AI adoption requires more than access to advanced models. Organisations need transparency, control, and the ability to adapt AI solutions to their specific operational requirements. Open sourcing Weam addresses these fundamental needs,” said Weam’s leadership team.

Weam’s open source platform aims to eliminate AI silos within large organisations by creating a unified environment for collaboration. It allows teams to share proven methodologies, deploy custom agents, and maintain full transparency across workflows, removing redundancies and accelerating enterprise-wide AI implementation.

Built on a modern technology stack—Next.js for the frontend, Node.js for the backend, and containerised Docker deployment—the platform integrates seamlessly with major AI providers such as OpenAI, Anthropic, Gemini, Llama, and Perplexity. Ongoing developments include Model Context Protocol (MCP) integration and a library of deployable enterprise AI applications.

“Weam represents India’s contribution to democratising enterprise AI adoption on a global scale,” said the company’s leadership. “This initiative transcends product development; we are cultivating a movement focused on transparent, collaborative AI implementation that empowers organisations rather than creating vendor dependencies.”

The company’s roadmap includes advanced agent capabilities and an open AI marketplace. Weam’s complete source code is available now on GitHub, free for all organisations to deploy without restriction.

China’s Ant Group unveils the Ling-1T LLM with a trillion parameters

Ant Group, the Chinese fintech powerhouse affiliated with Alibaba Group Holding, has launched Ling-1T, an open source, trillion-parameter large language model (LLM) that sets a new benchmark in complex reasoning, mathematics, and software intelligence.

Google open sources MCP server for analysing ads data

Google has officially open sourced the Google Ads API Model Context Protocol (MCP) server, now available on GitHub. This move allows AI applications to access and analyse Google Ads data using natural language for the first time, bridging AI models directly with real-world marketing workflows.

The MCP server is currently read-only, designed for diagnostics and analytics. Developers can integrate it into any MCP-compatible AI system to securely retrieve insights from Google Ads accounts, streamlining campaign analysis and reporting.

The release is built on the Model Context Protocol (MCP), an open standard that enables large language models to interact with external applications using natural language. By leveraging this open standard, AI developers can experiment, innovate, and integrate freely, without proprietary restrictions.

The open source MCP server unlocks new possibilities for automation, reporting, and analytics, with future versions expected to expand beyond read-only capabilities, potentially enabling AI-driven optimisation or campaign management directly through MCP integrations.

By releasing the MCP server as open source, Google is encouraging community contributions, accelerating innovation and expanding functionality faster than a closed proprietary model. The development represents a significant step in making AI tools more practical, accessible, and integrated into marketing operations.
