

Debian 13.0 'Trixie' released, featuring Linux 6.12 LTS and official RISC-V support

The Debian Project has officially announced the release of Debian 13.0 'Trixie', the latest stable version of the popular GNU/Linux distribution. Released on its traditional two-year cycle, Debian 13 delivers a wide range of updates, new features, and expanded hardware support.

At its core, Debian 13 ships with the Linux 6.12 LTS kernel, ensuring long-term stability and hardware compatibility. The distribution defaults to the GNOME 48 desktop environment and makes use of the GCC 14.2 compiler, alongside significant package upgrades including OpenJDK 21, Python 3.13, and numerous other updated tools and libraries.

A key milestone in this release is the official support for the riscv64 architecture. For the first time, Debian fully supports 64-bit RISC-V hardware, giving developers and users access to the complete Debian package ecosystem. This advancement marks a major step for the open source RISC-V instruction set architecture, which has been gaining momentum across embedded systems, IoT devices, and data centre deployments. By qualifying the platform for production use, Debian strengthens RISC-V's position as a viable alternative to proprietary architectures.

Debian 13 also introduces a new approach to handling temporary files. Fresh installations now configure `/tmp` as a `tmpfs`, storing temporary files in RAM instead of on disk for improved performance. To prevent storage clutter, files in `/tmp` are automatically deleted after 10 days of inactivity, while `/var/tmp` files are cleaned after 30 days. This aligns Debian with practices already adopted by other major distributions, though users with limited memory should account for the additional RAM usage.

Debian 13.0 'Trixie' is available now for download at cdimage.debian.org.

newsgroups. Fixes also cover specific issues such as deleting messages in 'Group by Sort' view, handling `mailto:` links with signed messages, displaying WebP contact photos from CardDAV servers, and posting to newsgroups.

Other corrections include resolving problems with localised folder creation, long initial load times, backspace behaviour in the quick filter field, archiving of RSS messages, and reply failures tied to configuration options.

Finally, Thunderbird 142 introduces visual and user experience refinements, while addressing seven security vulnerabilities, strengthening the overall stability and security of the client.

With its mix of new functionality, quality-of-life improvements, and critical fixes, Thunderbird 142 promises to enhance the reliability and versatility of one of the most widely used open source email platforms.

KDE Gear 25.08 features significant performance enhancements

The KDE Project has announced the release of KDE Gear 25.08, the latest stable version of its open source application suite designed for the KDE Plasma desktop environment and GNU/Linux distributions. This update delivers new

features, usability improvements, and performance enhancements across a wide range of KDE applications.

The Dolphin file manager gains two new search engines, making it easier to locate

elusive files and folders, along with a new option to open Filelight directly from the 'Tools' menu and additional controls for the 'View Mode' switching button.

The KDE Itinerary travel assistant now allows manual entry of train and bus trips, introduces automatic departure updates, and expands its alternative connections search to include ferries and flights. Meanwhile, KOrganizer adds a date picker for faster navigation and improved search field tooltips, while the Kleopatra certificate manager now supports opening multiple notepads simultaneously.

Messaging and communication tools also receive key updates. NeoChat, the Matrix client, introduces poll creation and per-thread context menus. The Angelfish mobile web browser now allows users to disable its built-in adblocker, offering flexibility for those who wish to support content creators.

Other improvements include support for the Greek alphabet in the classic KHangman spelling game, full Plasma 6 compatibility for the Artikulate pronunciation trainer, and expanded non-European alphabet support in the Krfb remote desktop app. The Akonadi engine also sees a major efficiency boost, reducing memory usage by around 75%.

In addition to these highlights, KDE Gear 25.08 incorporates numerous smaller refinements, bug fixes, and performance patches. Users can expect packages to become available soon in the stable repositories of their preferred GNU/Linux distributions.
