

importance to leverage open innovation opportunities to provide richer customer experiences.

**Q. How can a company effectively manage innovation, brand positioning, market presence, and technology stack within their overall workflow and architecture?**

**A.** Today, to make businesses successful and drive differentiated value propositions, experimentation is critical. Open source technology plays an important role in providing opportunities for experimentation, democratising the process, and making it more iterative and pervasive. The rapid evolution of technology, especially in the cloud and open source domain, has accelerated experimentation.

Architectures are designed with cost optimisation in mind, reflecting customers' changing priorities. The contemporary customer introduces four dimensions of cost in the context of providing cost optimisation services. The first dimension revolves around measurement, billing, and accounting. The second focuses on sales and exploring avenues for cost optimisation. The third dimension is centred on planning, involving forecasting and future-oriented design. Creating a culture and framework for cost-optimised operating models constitutes the fourth dimension. All these things are feasible and more streamlined due to the widespread adoption of open source technologies, which seamlessly connect with industry trends.

**Q. How do companies gauge what open source libraries to utilise?**

**A.** This is a critical question, and as mentioned earlier, certain aspects need attention quicker than specific products. Regarding credibility and usage, consider a scenario where I employ a pre-existing model from a third-party foundation as part of my

services. If that model doesn't align with my compliance requirements, it must be customised to meet those specific business needs. While open source technology is valuable, it's essential to recognise that it may not always perfectly fit my compliance and customer service requirements. Therefore, a nuanced approach is necessary to address the dynamic aspects that come to life in this context.

**Q. Who assumes responsibility for maintaining the updates from the third-party open source library, software usage, and regular updates?**

**A.** Navigating through the organisational vision due to the internal management of open source libraries demands establishing appropriate policies and procedures. As you rightly pointed out, determining who manages the updates is the challenge. We must implement an education mechanism and specific policies to ensure that the tools used align seamlessly with the organisation's project goals. Without the right guidance, policies, and procedures, there's potential for trouble. Drawing the line in this context is crucial, and this is where partnerships play a pivotal role. Open source service providers, like the community village, offer valuable assistance, aiding organisations in carefully delivering and integrating updates. While this might be somewhat complex, the best defence today lies in having well-defined policies and procedures within the organisation and forming a structured process.

**Q. What strategies can be employed to select licences for open source systems to maintain openness while preventing misuse or exploitation?**

**A.** There are a lot of rules around licensing technology. There is no one-size-fits-all licensing strategy

in the open source world. There are two main types of open source licences – permissive and copyleft. The latter specifies how the open source software can be used, modified and distributed. I've also seen open source code generation tools using line-of-code-based licensing models. Yet, challenges arise when code analysis breaks down or when making the tools available to users on their platform of choice. There are also flexible licensing models where options like user-level or usage-based pricing strategy are followed catering to users' varying needs, whether they're part of a large enterprise or individuals working from a local coffee shop. There's no universal answer for licensing, but there is a definite need to formulate strategies that can be standardised across the community.

**Q. How does AWS leverage open source AI/ML solutions?**

**A.** AWS is a proven leader in AI/ML solutions and can help solve real world business problems in any industry. Organisations can innovate with confidence by building on 20+ years of experience at Amazon. AWS AI/ML solutions increase productivity of data scientists multi-fold, who can now focus their efforts on improving customer experiences, optimising business processes and accelerating innovation. In short, it helps them create impactful solutions faster. You can use ready-made, purpose-built AI services, or your own models with AWS ML services. This can be used to create more intelligent contact centres, detect fraud and personalise user experiences, and much more. We unlock the potential of GenAI by offering the most performant infrastructure for it with the flexibility to build your own foundation models, and by making GenAI powered applications available on AWS cloud. **END**
