

— just add the texts in the form of a list into the code, as shown below:

```
from googletrans import Translator
translator = Translator()
translation=translator.translate(['मेरा नाम जिष्णु'])
for a in translation:
    print(a.origin, ' -> ', a.text)
print(translation)
```

The output, given below, shows that it gives us separate translations for each string:

```
[(base) Jishnu-MacBook-Air: downloads jishnusaaurav$ python
translation.py
मेरा-> My
नाम-> Name
जिष्णु-> Jishnu
[<googletrans.models.Translated object at 0x1102c1350>,
<googletrans.models.Translated object at 0x1102d1290>,
<googletrans.models.Translated object at 0x1102dcb90>]
(base) Jishnu-MacBook-Air: downloads jishnusaaurav$
```

We can also use this library to detect languages by using the following code:

```
from googletrans import Translator
translator = Translator()
translation=translator.detect('मेरा')
print(translation)
```

In the output shown below, we can see that the language is detected and the confidence of how right that prediction is, is also shared with us.

```
(base) Jishnu-MacBook-Air: downloads jishnusaaurav$ python
translation.py
```

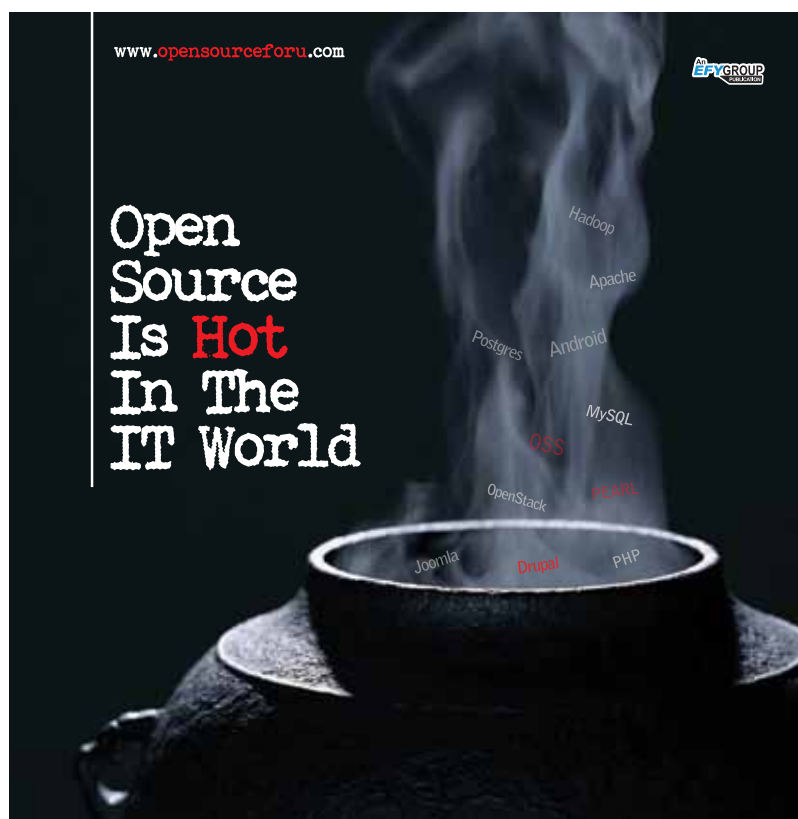

```
Detected (lang=hi, confidence 0.98828125)
```

```
(base) Jishnu-MacBook-Air: downloads jishnusaaurav$
```

That's it, you have learnt how to translate from one language to another using a Google library. You can now explore more libraries that perform machine translation, compare them and choose the best one for your use case. This article can act as a foundation for your journey into the NLP machine translation field! **END** 🐧
