

IoT to IoE: The Importance of Security

With humongous amounts of data available on IoT devices in real-time, the connected world has become both exciting and challenging. Systems that prevent access to this data by unauthorised persons have become crucial. A few security principles have been spelt out to ensure a smart home that runs on connected devices is not invaded. Also, some very interesting trends are shaping the future of IoT solutions.

The Internet of Things (IoT) is dominating multi-disciplinary solutions in sectors like retail, manufacturing and healthcare. IoT services share data in real-time which is analysed and used for business processing. But for smarter solutions that span different industrial sectors, this may not be enough and unconventional solutions like Internet of Digital (IoD) and Internet of Humans (IoH) are needed.

Internet of Everything (IoE) is the amalgamation of IoT, IoD and

IoH. It helps to create a connection between people, smart devices and organisations, and is driven by four principles – people, data, things and process. New age architecture for interdisciplinary application design needs a ‘boundaryless’ approach. For example, an end-to-end solution for retail stores requires financial services, retail store monitoring services, order processing to manufacturing units, and inventory management.

Internet of Digital is the group of data service applications that handle
