

ChatGPT: It's Easy to Poison this AI Model

ChatGPT is still fragile and needs to be used with care. You can hoodwink it into thinking it is giving you information for the right reasons, and in the process, make security systems vulnerable.

by BlackBerry in North America, the UK, and Australia have predicted that a cyber attack attributed to ChatGPT will take place in less than a year. Seventy-five per cent of those surveyed claimed that ChatGPT is already being abused by foreign powers against other nations.

While the respondents in this poll believe that ChatGPT is employed for “good” reasons, 73 per cent recognise the potential threat it poses to cyber security and are either “very” or “fairly” worried. This shows that artificial intelligence (AI) is a double-edged sword.

Most of the offensive activity in the cyber security industry requires the attackers to build harmful

Artificial intelligence has revolutionised several industries, including cyber security, where it has improved security breach detection and prevention. This has been demonstrated by the chatbot ChatGPT, although subsequent abuses of the bot have raised questions about its ability to hurt in unanticipated ways. ChatGPT has been successfully poisoned by attackers. The potential for an AI-assisted kill chain is examined in this article along with the corresponding security risks.

OpenAI came up with the chatbot ChatGPT based on the architecture of GPT-3, a large multimodal model used to respond to follow-up queries, admit mistakes, dispute false premises, and more. ChatGPT is also known as GPT-3.5 since it is fine-tuned to answer most queries and continue conversations, as shown in Figure 1.

Following its introduction, many people rapidly began using ChatGPT for a variety of tasks, from writing articles to creating social media posts and captions. It provides suitable replies in a conversational

style using deep learning algorithms to comprehend the context and meaning of text input. This model can comprehend a wide range of topics and circumstances because it was trained on a huge data set of online content.

Over half (51 per cent) of the 1500 IT decision-makers surveyed
